AMERICAN MEDICAL ASSOCIATION, CHICAGO, 1939

OFFICERS OF THE AMERICAN MEDICAL ASSOCIATION—1939-1940

HEADQUARTERS OF THE ASSOCIATION, 535 N. DEARBORN ST., CHICAGO

GENERAL OFFICERS

PRESIDENT—ROCK SLEYSER	
PRESIDENT-ELECT—NATHAN B. VAN ETEN	Wauwatosa, Wis.
VICE PRESIDENT—ALPHONSE McMAHON	New York
SECRETARY AND GENERAL MANAGER—OLIN WEST	St. Louis
TREASURER—HERMAN L. KRETSCHMER	Chicago
SPEAKER, HOUSE OF DELEGATES—H. H. SHOULDERS	Chicago
VICE SPEAKER, HOUSE OF DELEGATES—R. W. FOUTS	Nashville, Tenn.
EDITOR—MORRIS FISHBEIN	Omaha
BUSINESS MANAGER—WILL C. BRAUN	Chicago

BOARD OF TRUSTEES

Ralph A. Fenton	Portland, Ore., 1940
James R. Bloss	Huntington, W. Va., 1940
Thomas S. Cullen	Baltimore, 1941
Arthur W. Booth, Chairman	Elmira, N. Y., 1942
R. L. Sensenich	South Bend, Ind., 1942
Austin A. Hayden, Secretary	Chicago, 1943
Charles B. Wright	Minneapolis, 1943
Roger I. Lee	Boston, 1944
E. L. Henderson	Louisville, Ky., 1944

JUDICIAL COUNCIL

G. E. Follansbee, Chairman	Cleveland, 1940
Walter F. Donaldson	Pittsburgh, 1941
Holman Taylor	Fort Worth, Texas, 1942
John H. O'Shea	Spokane, Wash., 1943
Edward R. Cunniffe	New York, 1944
Olin West, Secretary, ex officio	Chicago

COUNCIL ON MEDICAL EDUCATION AND HOSPITALS

John H. Musser	New Orleans, 1940
Fred Moore	Des Moines, Iowa, 1941
Reginald Fitz	Boston, 1942
Fred W. Rankin	Lexington, Ky., 1943
Charles Gordon Heyd	New York, 1944
Frank H. Lahey	Boston, 1945
R. L. Wilbur, Chairman	
Stanford University, Calif., 1946	
W. D. Cutter, Secretary	Chicago

COUNCIL ON SCIENTIFIC ASSEMBLY

A. A. Walker	Birmingham, Ala., 1940
S. P. Mengel	Wilkes-Barre, Pa., 1941
Clyde L. Gummer	Cleveland, 1942
James E. Paullin, Chairman	Atlanta, Ga., 1943
J. Guiney Taylor	Milwaukee, 1944

AND EX OFFICIO

The President-Elect, the Editor and the Secretary of the Association.

COUNCIL ON PHARMACY AND CHEMISTRY

(Standing Committee of Board of Trustees)	
Morris Fishbein	Chicago, 1940
G. W. McCoy	Washington, D. C., 1940
Perrin H. Long	Baltimore, 1940
Elmer M. Nelson	Washington, D. C., 1940

Torald Sollmann, Chairman	Cleveland, 1941
W. C. Rose	Urbana, Ill., 1941
E. L. Sevringhaus	Madison, Wis., 1941
E. M. K. Geiling	Chicago, 1942
W. W. Palmer	New York, 1942
S. W. Clausen	Rochester, N. Y., 1942
R. A. Hatcher	New York, 1943
E. E. Irons	Chicago, 1943
H. N. Cole	Cleveland, 1943
Stuart Mudd	Philadelphia, 1943
J. Howard Brown	Baltimore, 1944
C. W. Edmunds	Ann Arbor, Mich., 1944
David P. Barr	St. Louis, 1944
Paul Nicholas Leech, Secretary	Chicago

COUNCIL ON PHYSICAL THERAPY

(Standing Committee of Board of Trustees)

Howard T. Karsner	Cleveland, 1940
Frank R. Ober	Boston, 1940
Frank D. Dickson	Kansas City, Mo., 1940
A. U. Desjardins	Rochester, Minn., 1941
H. B. Williams	New York, 1941
Frank H. Krusen	Rochester, Minn., 1941
Ralph Pemberton	Philadelphia, 1942
Harry E. Mock, Chairman	Chicago, 1942
Anthony C. Cipollaro	New York, 1942
W. E. Garrey	Nashville, Tenn., 1943
W. W. Coblenz	Washington, D. C., 1943
John S. Coulter	Chicago, 1943
Olin West, ex officio	Chicago
Morris Fishbein, ex officio	Chicago
Howard A. Carter, Secretary	Chicago

COUNCIL ON FOODS

(Standing Committee of Board of Trustees)

Irvine McQuarrie	Minneapolis, 1940
Morris Fishbein, Chairman	Chicago, 1940
R. M. Wilder	Rochester, Minn., 1941
Howard B. Lewis	Ann Arbor, Mich., 1941
J. S. McLester	Birmingham, Ala., 1941
Philip C. Jeans	Iowa City, 1942
Mary Swartz Rose	New York, 1942
Lydia J. Roberts	Chicago, 1943
George R. Cowgill	New Haven, Conn., 1943
C. S. Ladd	Bismarck, N. D., 1944
Tom D. Spies	Cincinnati, 1944
Franklin C. Bing, Secretary	Chicago

COUNCIL ON INDUSTRIAL HEALTH

(Standing Committee of Board of Trustees)

Stanley J. Seeger, Chairman	Milwaukee
Harvey Bartle	Philadelphia
L. D. Bristol	New York
Warren F. Draper	Washington, D. C.
Leroy U. Gardner	Saranac Lake, N. Y.
H. H. Kessler	Newark, N. J.
A. J. Lanza	New York
A. D. Lazenby	Baltimore
Robert T. Legge	Berkeley, Calif.
Earl D. Osborne	Buffalo
C. W. Roberts	Atlanta, Ga.
C. D. Selby	Detroit
C. M. Peterson, Secretary	Chicago

COMMITTEE ON SCIENTIFIC EXHIBIT

Thomas S. Cullen, Chairman	Baltimore
Roger I. Lee	Boston
E. L. Henderson	Louisville, Ky.
Thomas G. Hull, Director	Chicago

ADVISORY COMMITTEE

D. Chester Brown	Danbury, Conn.
George Blumer	New Haven, Conn.
Paul J. Hanzlik	San Francisco
Ludvig Hektoen	Chicago
Urban Maes	New Orleans
Eben J. Carey	Milwaukee
James P. Leake	Washington, D. C.

SECTION OFFICERS

PRACTICE OF MEDICINE—Chairman, William S. McCann, Rochester, N. Y.; Vice Chairman, William B. Porter, Richmond, Va.; Secretary, Fred M. Smith, University Hospitals, Iowa City.

SURGERY, GENERAL AND ABDOMINAL—Chairman, Thomas M. Joyce, Portland, Ore.; Vice Chairman, W. Barclay Parsons, New York; Secretary, Arthur W. Allen, 264 Beacon Street, Boston.

OBSTETRICS AND GYNECOLOGY—Chairman, Ludwig A. Emge, San Francisco; Vice Chairman, Buford G. Hamilton, Kansas City, Mo.; Secretary, Norman F. Miller, 1313 East Ann Street, Ann Arbor, Michigan.

OPHTHALMOLOGY—Chairman, Harry S. Gradle, Chicago; Vice Chairman, Everett L. Goar, Houston, Texas; Secretary, Derrick Vail, 441 Vine Street, Cincinnati.

LARYNGOLOGY, OTOTOLOGY AND RHINOLOGY—Chairman, Arthur W. Proetz, St. Louis; Vice Chairman, F. T. Hill, Waterville, Maine; Secretary, LeRoy A. Schall, 403 Commonwealth Avenue, Boston.

PEDIATRICS—Chairman, Albert D. Kaiser, Rochester, N. Y.; Vice Chairman, Philip M. Stimson, New York; Secretary, Hugh L. Dwyer, 315 Alameda Road, Kansas City, Mo.

PHARMACOLOGY AND THERAPEUTICS—Chairman, Irving S. Wright, New York; Vice Chairman, C. M. Gruber, Philadelphia; Secretary, Edgar V. Allen, 102 Second Avenue S.W., Rochester, Minn.

PATHOLOGY AND PHYSIOLOGY—Chairman, Frank W. Hartman, Detroit; Vice Chairman, J. J. Wiggers, Cleveland; Secretary, J. J. Moore, Street, Chicago.

NERVOUS AND MENTAL DISEASES—Chairman, Paul C. Bucy, Chicago; Vice Chairman, John F. Fulton, New Haven, Conn.; Secretary, Johannes M. Nielsen, 727 West Seventh Street, Los Angeles.

DERMATOLOGY AND SYPHILOLOGY—Chairman, John G. Downing, Boston; Vice Chairman, Richard S. Weiss, St. Louis; Secretary, C. F. Lehmann, 705 East Houston Street, San Antonio, Texas.

PREVENTIVE AND INDUSTRIAL MEDICINE AND PUBLIC HEALTH—Chairman, Harold S. Diehl, Minneapolis; Vice Chairman, Clarence D. Selby, Detroit; Secretary, W. A. Sawyer, 343 State Street, Rochester, N. Y.

UROLOGY—Chairman, Frederic E. B. Foley, St. Paul; Vice Chairman, Meredith F. Campbell, New York; Secretary, Vincent J. O'Connor, 55 East Washington Street, Chicago.

ORTHOPEDIC SURGERY—Chairman, Robert V. Funsten, Charlottesville, Va.; Vice Chairman, J. Albert Key, St. Louis; Secretary, Guy A. Caldwell, 1640 State Street, New Orleans.

GASTRO-ENTEROLOGY AND PROCTOLOGY—Chairman, A. H. Aaron, Buffalo; Vice Chairman, Frank C. Yeomans, New York; Secretary, J. A. Bagen, 102 Second Avenue S.W., Rochester, Minn.

RADIOLOGY—Chairman, Merrill C. Sosman, Boston; Vice Chairman, Raymond C. Beeler, Indianapolis; Secretary, John T. Murphy, 421 Michigan Street, Toledo, Ohio.

CHILD HEALTH IN NATIONAL DEFENSE

CHAIRMAN'S ADDRESS

EDWARD CLAY MITCHELL, M.D.

MEMPHIS, TENN.

The title of "Child Health in National Defense" was chosen for my theme in this address because it is obvious that the future of our nation depends more on the coming generations than on any other factor. Ours is a declining population. Stuart Chase, in the February *Atlantic Monthly*, states that there are more than a million empty desks in the elementary schools of the United States this year. In 1930 the total enrolment was 21,300,000; in 1938 it had fallen to about 20,000,000. It is impossible today to consider democracy without considering youth, as it should be impossible to consider children without considering democracy. "For the aim of democracy is the development of human personality through the process of growth in an atmosphere of freedom." In a democracy such as ours we cannot enforce Hitler's regimen of forced parenthood, but with so great a decline in population we should realize that now we must make a greater effort to conserve and protect the health of our American children. We may have wealth, we may have guns and other munitions, but unless we have men, America will not survive.

If we are to determine whether our nation is advancing along the road toward democracy, which is a way of life and not a completed achievement, we must review the conditions surrounding children, the opportunities open to them, and the safeguards afforded them. And if we wish to test ourselves to determine whether in our own lives we are following the ethics of freedom, we can do no better than to test our attitudes toward the individual children with whom we come in contact and toward all the children for whom we share responsibility as citizens of a local community, our state and the nation.

This presentation will embrace, first, a review of the role the American physician has played in the past in national defense; second, how the physician can best serve the public in this great peace movement, which is probably more important as a means of national defense than in actual time of emergency of war; and, finally, a discussion of the various phases of health, including all those measures which will reduce infant mortality and give the future citizens a healthy body and a healthy mind.

THE AMERICAN PHYSICIAN IN NATIONAL DEFENSE

In 1918, 19,692 physicians left their practices and entered the service of the United States. These volunteers included men of all ages, from the recent graduate to physicians beyond 50 years of age. The specialists with the largest income offered their services. From my personal knowledge I know that many physicians paid more in income tax the first six months they were in service than they received from the government in salary. They entered the training camps, were drilled and, as many of you know, were made to police their own camps. This was a hardship but there were no complaints. Nor was their position without danger. Many were killed and a large number were unable to return to their practices because of physical disability incurred as a result of disease or actual wounds received in battle. Many returned home to find their practices lost. In numerous instances it took years to rebuild this practice, and as a result their families suffered.

After the war, many physicians in the service were not satisfied to go back to the rural communities to practice medicine. The government offered short post-graduate courses. As a result, many became specialists and practiced in the cities. This left a dearth of general practitioners and a dearth in rural medical care. This situation has now been materially improved, largely through the efforts of the American Medical Association.

The medical student is being trained first to be a physician capable of giving good service in all branches of medicine and surgery. Before qualifying as a specialist, applicants must have at least five years' preparation and then must pass a rigid examination. This protects the public by increasing the number of general practitioners and insures the training of those recognized as specialists.

On March 1, 1939, there were 112,210 physicians enrolled on the official membership of the American Medical Association. There are in the United States 2,205 physicians who limit their practice to pediatrics. Of this number 1,006 have been certified by the American Board of Pediatrics. In addition, the records show that there are 2,166 general practitioners who have declared themselves as especially interested in pediatrics yet do not limit their work to this field. The number of specialists is therefore small. Thus the responsibility for the success of our endeavors to promote child health falls largely on the family doctor not only because he is available in every community of the United States but because he has the confidence of the people. The pediatricians or specialists in other fields, while necessary, are too few to solve this problem other than in an advisory capacity.

HOW THE PHYSICIAN CAN BEST SERVE
THE PUBLIC

Legislative and municipal control, while helpful, have not solved and in the very nature of the case cannot be expected to solve the complex details of the problem of child health, when the problem is measured in nationwide dimensions and when the nation is a democracy. I believe that an effective first step toward our objective is a coordinated program of education of the public in accepted methods of immunization and in the newer knowledge of general care and nutrition of the child. This must be the task not of the obstetrician or of the pediatrician or of any one special group of lay or professional instructors, but of every physician, especially the general practitioner in his individual contacts.

A few years ago region II of the American Academy of Pediatrics held a joint meeting with all the state and many of the city health commissioners of the South. It was the opinion of those who attended this gathering that the health official could best serve by devoting his efforts and also his available funds to a plan of education. They further stated that they could spend their budget to better advantage not only for the education of the public but for education of their own personnel of physicians and nurses. When each physician becomes health minded to the extent of advising his own clientele, results would improve because of closer cooperation between the health official and the practicing physician and there would be less friction.

The prevailing teaching now is to keep the child well. The young physician is being encouraged to act as an adviser to his clientele in all health matters. Summary postgraduate courses are being instituted with particular emphasis on the maternal, antepartum aspects and care of the well child.

Every American child deserves, if possible, and the interests of the state demand a healthy body and a proper environment. In fact, a vital consideration in any plan of national defense is the physical quality no less than the psychologic stamina of its citizenship. The physical quality of the adult citizen is largely determined by prenatal factors—a good inheritance and early childhood care.

In this connection it seems appropriate to mention a project which has been undertaken by the American Legion, which has adopted child health as one of its major projects. It has been demonstrated to this body that this is one of the means of protecting our great democracy, of promoting national defense. Hitler and Mussolini did not begin to work at once; they began to develop the youth of their countries, first, to give a strong body, then to raise them as nationalists from the beginning; thus, after several years their strongest support is in the young men, the coming generation. While we do not wish to create a race of "goose-steppers," we should be concerned over the fact that we are not altogether raising a race of Americans. Those who wish to weaken us are smart enough to realize that insinuating propaganda should be begun during childhood, that as the child is raised so will he remain; that early impressions are lasting.

When the British conscription act was announced late in April the German press was amused and sarcastic—the substance of what they said was this: "The English conscript is physically the worst in Europe."

FIVE YEAR PLAN OF THE AMERICAN LEGION

The American Legion is very much interested in a five year plan. The first year's work is devoted to disease prevention embodying a sort of modification of the

Indiana Immunizing Plan, the second year to nutrition and its problems. The third year the physically handicapped child will be considered. The fourth and fifth years are left open so that the planning committee may be in a position to take advantage of the discoveries of the first, second and third years in order that it may more properly advise the work of the fourth and fifth years.

This plan should be considered in its broadest sense: that of producing a better next generation. The American Legion has approximately 1,000,000 members. The Auxiliary has 464,865. There are 11,506 posts. At the present time they are starting the Sons and Daughters of the Legion. They are represented in every town and in many villages and rural communities. They have the affiliated organization of the Forty and Eight, which is also strong. The Auxiliary, particularly, is interested in child health and wishes instruction. The potentiality of such an organization is obvious if its energies are rightly directed. One can also see what might happen if those energies were directed into the wrong channels.

The program contemplated by the American Legion has been to appoint a central committee to suggest a general plan for each year, taking up each year the one phase of child health that seems most urgent; to adopt a five year plan, working with the existing organizations, and then next year take up another plan. Physicians should have a general plan each year but administer it separately through the states, because, as has been explained, we have the same problems but not the same method of approach. Let us take up through their various states and local posts this subject, making it a purely educational program. Let us put these women particularly to work in their various communities. If necessary, let them make a house to house canvass.

The subjects for especial consideration for this next year are:

1. Conservation of the child's own home for the child.
2. Eradication of congenital syphilis in children, particularly through antepartum and maternal care.
3. Insurance of child health.
4. Control of communicable diseases.

While each state has its separate program, these especially selected yearly subjects should be nationally considered. The month of April is emphasized as "Legion Child Welfare Month." There is a general meeting in Indianapolis for the purpose of studying the need, the results accomplished, and outlining a program for the coming year.

At this point I should like to call attention to certain happenings that occur in every community often assuming many of the attributes of an undiluted racket. I refer to the "baby show," where on some occasions hundreds of children are brought together. It is under these conditions that the communicable diseases are bred, and these gatherings of babies for exhibition are of no advantage whatever to any one. There is often a solicitation of funds, which is, of course, the primary purpose of the baby show. And these solicitations of funds for an indefinite purpose, though ostensibly connected with a phase of child health, cannot be too severely condemned. It is in connection with these solicitations that large amounts of money are raised and wasted that might be put to so much better use.

I feel that I should suggest too that the poorly trained social worker and the improperly trained nurse repre-

sent conditions that should be carefully examined into. Too much public money is raised, spent and wasted on undertakings lacking a definite plan. We are experimenting too much—not too little—ill advised research when work of far more valuable character is overlooked. There is the work of Dr. Tom D. Spies at Birmingham, Ala. Dr. Spies is doing a remarkable piece of work in the field of nutritional disorders of Southern children, particularly among the economic underprivileged who are unable to obtain proper foods and are suffering from pellagra and allied disorders. Yet this most valuable work is poorly supported while you and I know of millions that are wasted in nearly worthless research.

I feel that it is very proper in a paper of this character, where I am positively pointing out what should be done, that I, at the same time, should in a negative sense point out certain practices and certain happenings that must be, in the interest of child welfare, eliminated.

Every community has very similar problems in health, but communities differ in their solution to these problems. In Memphis we have a health problem which is geographic—any statistical measurements are apt to be misleading. From the states of Arkansas and Mississippi, as well as from communities in West Tennessee, come patients who use our hospital facilities, resulting in a death incidence that has no relation to our local conditions. Our child mortality was very high, but this percentage is influenced by neighboring states making use of our facilities rather than a serious local unexplained child health condition.

Then in all Southern communities there is our accentuated health problem that a Negro population presents. Improved sanitation, improved living conditions and free public clinics are making their contribution to the welfare of the Negro child. But the surface is hardly scratched—there is much work to be done.

The American Legion states that "socialized medicine" has become a very controversial subject. The American Legion cannot enter on the controversial elements of this subject. However, there is no controversy on the subject of community and individual protection and prevention of disease and adequate care of the child. A program acceptable and suitable to use both by the medical profession and by lay groups must be practical and simple in its application.

In April, at the White House, President Roosevelt as honorary chairman formally opened the fourth of a series of national conferences on child welfare held in Washington under presidential auspices at intervals of approximately ten years. Experts and social workers with a wide variety of experience and interest in children's problems considered "the objective of a democratic society in relation to children; the essentials which such a society must provide for children if they are to be happy and society is to be secure; the meaning of our social institutions as they appear to the child; the need that he has to find joy and zest and purpose in living, to look forward to the time when he will play his part in his community and his country."

PRACTICAL BASIS FOR IMPROVING CHILD HEALTH

Probably we have been approaching the subject of "child welfare" in the wrong manner; it seems to me that we have been attempting to build the house before laying the foundation, that in the past too much of our philanthropy has been misdirected, that sentimentalism rather than the practical realities of children's health problems have dominated. For these reasons my purpose is to reduce the whole problem of child health to

such a practical basis that it may be related to national defense, to a fuller democratic life and to a proper educational appreciation.

There are three classes of persons in the United States—the well-to-do, the great middle class and the indigent. The well-to-do are solving their own problem but still can be benefited by proper instruction. The poor are being taken care of by local, state and national assistance. But the great middle class, the backbone of the nation, are the ones most neglected. By beginning with the child, giving him a healthy body from birth, immunizing against disease, much illness with its high cost during the period of growth will be eliminated. The great middle class is only too willing to give their children every protection if properly instructed.

Does this great class dream of what their children will be like? "How can they be imbued with ideals which will guide them in decades which may be more difficult than that in which we now live? Will our civilization present to them values which will seem to warrant effort and sacrifice? Will it offer to them hope in an emerging justice, a basic security on which they can build lasting personal relationships?"

"These questions cannot be solved by any group of people in any single year. If the Conference on Children in a Democracy and the program adopted by the American Legion help us to define those basic values in a free society which must be cherished and defended at whatever cost, from generation to generation, they will have served the purpose which the President and the members of the American Legion have set before them."

The American Medical Association was organized in 1847 for the purpose of providing medical care for the people of the United States. It has through its members outlined medical education, controlled medical practice. The bulk of its members is composed of the practicing physician, the family doctor.

Finally, I wish to appeal to the members of the American Medical Association to accept the responsibility of child health education in their respective communities; to the specialists to assist by giving the family physician and his clientele the benefit of his special knowledge; to the people themselves to consider carefully before they listen to certain propaganda which classifies this great association as a trust or octopus that should be destroyed, for fear that they might destroy, instead of an octopus, a friend who has striven for many years to provide the best of medical care.

In concluding, I would like to summon the medical profession—the specialists, the general practitioner, the social worker, the nursing profession, the welfare associations—in fact, all of those groups definitely interested in the improvement of child health and child life to combine so that their combined influences may eliminate from our American life disease, ignorance, poverty, propaganda and politics.

1073 Madison Avenue.

Clinical Omniscience.—In the attempt at clinical omniscience, learning drifts into superficialities and is not profound, for there is little time for critical weighing, for sorting, or comparison, and therefore there is little correlation of observation and simplification of ideas. Intensive clinical training, as this exists, leads in general to no real grasp of the problems set by disease or of means of solving them; it is too purely observational for this.—Lewis, Sir Thomas: *Research in Medicine and Other Addresses*, London, H. K. Lewis & Co., Ltd., 1939.

MARIHUANA: A PSYCHIATRIC STUDY

WALTER BROMBERG, M.D.

Psychiatrist-in-Charge, Psychiatric Clinic, Court of General Sessions;
Senior Psychiatrist, Bellevue Hospital
NEW YORK

For almost ten years, marihuana smoking in the United States has engaged the attention of police officials, narcotic officers, prosecutors, judges and physicians. With its spread, the attention given marihuana in the press has increased. It is frequently a theme in contemporary literature; even the stage and screen have exploited its theatrical possibilities.¹ It has been blamed in the press and by responsible officials for insanity, suicide and crime, especially among the youth of the country, and is fast attaining the position of a public enemy. In 1931 the International Narcotic Education Association in its Geneva convention acted to include marihuana (hashish) in an international treaty for the limitation of the distribution of narcotic drugs. The marihuana excise tax law was enacted by Congress and made effective Oct. 1, 1937. It makes the use of marihuana, except by qualified persons, illegal. The penal code, based on the uniform narcotic drug act in the public health law in New York, as in other states, classes marihuana (cannabis) with opium derivatives and cocaine, and its use or sale constitutes a crime.

In 1934² I reported eleven cases from the Bellevue Hospital of mental reactions induced by smoking marihuana and reviewed the literature on the subject. The present paper brings that material together and includes subsequent study of the problem and observations made since 1934.

The drug is a product of the flowering tops of the hemp plant (*Cannabis americana* or *Cannabis sativa*). In America the name marihuana, which is said to be a corruption of the Portuguese "maraguango," meaning intoxicant, is used. It has numerous picturesque names, such as muggles, reefers, Mary Warner, Indian hay, the weed and tea. The hemp plant, a tall bush with long green leaves, is cultivated for hemp fiber in the midwest and also grows wild throughout the nation. The method is to roll the dried flowering tops into cigars. The leaves and flowering tops of the plant are covered by a resin whose composition is unknown. Government chemists, especially Blatt,³ Wollner⁴ and Matchett, found five fractions in cannabiniol, the alleged active principle. The Beam test, hitherto regarded as specific in detecting the active principle chemically, has been found of no value. The chemistry of the drug needs and is undergoing thorough revision. However, for practical purposes, marihuana, hashish and cannabis may be considered synonymous.

Legend envelops the origin of the use of cannabis, and Walton⁵ has recently described its fascinating history. In the latter part of the nineteenth century and the decade beginning the twentieth century, there was a revival of interest in hashish as a substance for study-

ing sense perception in laboratories of experimental psychology. S. Weir Mitchell, William James and others worked with it.

Recently marihuana has been alleged to be the frequent cause of crime, such as assault, murder, rape and robbery, and of suicides,⁶ especially among young people. The Foreign Policy Association⁷ listed ten cases of atrocious crimes committed by persons under its influence. Frequent reference is made to a report by Eugene Stanley,⁸ district attorney of New Orleans, a hotbed of marihuana usage, in which he stated that, among 450 men indicted for major crime in New Orleans during 1930, 125 were marihuana addicts, slightly less than half the total number of murderers were addicts and from 18 to 20 per cent of all persons tried for larceny, robbery and assault were users of marihuana. The League of Nations subcommittee received a report from Dr. J. Bouquet,⁹ acknowledged to be a world expert on cannabis, in which he stated that "the use of cannabis, whether smoked or ingested in its various forms, undoubtedly gives rise to a form of addiction which has serious social consequences (abandonment of work, propensity to theft and crime, disappearance of reproductive power)."

The experience which forms the basis of this paper was gathered in the Bellevue Hospital and the Psychiatric Clinic of the Court of General Sessions (having jurisdiction over felonies in New York County) over a period of six years. Persons brought to the hospital are those showing overt mental symptoms; hence the vast proportion of marihuana smokers in New York City probably do not reach medical hands.

PSYCHIATRIC OBSERVATIONS

There has been considerable literature on the intoxication and insanity-producing effect of cannabis in papers from Asia,¹⁰ Europe¹¹ and the United States.¹² To sum up this material, it can be said that the syndromes are of three types: (a) intoxication, (b) toxic psychosis, with or without an admixture of other types of mental reactions (schizophrenic, manic-depressive), and, according to Eastern European and Asiatic observers, (c) chronic dementia and deterioration following prolonged use. Apparently the third type, a deteriorating process, has not been observed in American clinics.

My experiences with mental conditions following the use of marihuana indicate that there are two categories of mental reaction: (1) acute intoxication (marihuana psychosis), containing sensory, motor and subjective elements, lasting from several hours to several days, often with anxiety or hysterical reactions, and transient panic states or depressions, and (2) toxic psychoses, including (a) those in which there are many admix-

tures of a disturbed sensorium with delusional and emotional reactions amounting to a psychosis, but with the common characteristic toxic signs, and (b) atypical functional psychoses which are initiated by marihuana or colored by marihuana in their symptoms but continue in the form of the underlying psychosis, the marihuana-induced state apparently representing an incipient stage in the psychosis. There were fourteen cases of acute intoxication and seventeen of toxic psychosis in our series (table 1).

1. *Acute Intoxication (Marihuana Psychosis).*—The distinction between acute intoxication due to marihuana and psychosis due to marihuana depends on the severity of the symptoms. Acute intoxication, induced by smoking from one to four cigarettes, brings about after an interval varying from one half to five hours one or all of the following symptoms: an increase in motor activity, a feeling of excitement, mental confusion, disorientation, crowding of perception, elementary visual illusions and hallucinations, euphoria and talkativeness. In addition, numerous subjective experiences occur, such as increased speed of thought processes, a feeling of intellectual brilliance, change in time perception, various somatic feelings, hunger, dizziness, a feeling of swelling of the head, lightness of the extremities, a sensation of walking on air, lengthening of the limbs and sexual illusions. Usually the sexual excitement is caused by the fact that the possible sexual objects become extraordinarily desirable. It is not so much a matter of increased potency as of increased reaction to sexual fantasies and illusions. One patient said "I saw black and white women lying in bed with legs separated, as if expecting men . . . some women in the park with nothing on, doing nasty dances, moving their hips. I chased after them." Others stated that women appeared amazingly beautiful. One patient said "In the subway I felt very sexy. I wanted to touch every woman who passed."

The speeded-up physical motility has its counterpart in rapid speech. There is a feeling on the part of the subject that he is witty, even brilliant; his ideas flow quickly and words come readily to his tongue. Conclusions and answers seem to come to mind ready formed and surprisingly clear, without the effort of thinking. This feeling of clarity is of course spurious. Actually the productions of the intoxicant are hard to follow, for when the subject wishes to explain what he has thought there is only confusion. The rapid flow of ideas gives a subjective impression of brilliance of thought and observation. The sense of increased speed of thinking apparently has an effect on memory; hence the confusion that appears when the subject tries to recall what was thought during the intoxication.

The smoker finds it pleasant to be with others and to impart his experiences to them. This is reflected in the fact that marihuana is ordinarily smoked at parties or in groups. It is felt that this need for a social setting is a reaction to an inner anxiety arising from the threat of bodily destruction implied in somatic illusions induced by marihuana. In the ordinary case of marihuana smoking, especially when the subject is used to the drug, this threat becomes converted to euphoria, which develops to uncontrollable fits of laughter. Nevertheless inquiry shows that almost every smoker is aware of definite uneasiness at the outset of the intoxication. The descriptions from smokers in Harlem and from experimental subjects agree on this point. In the words of a user of two years' standing, initiates "shrink together, feel tight inside and get frightened."

After they smoke it more than once, the reality of these frightening somatic illusions becomes less. In occasional instances, and these are the cases which are apt to come to medical attention, the anxiety with regard to death, insanity, bodily deformity and bodily dissolution is startling. The patient is tense, nervous, frightened; a state of panic may develop. Often suicide or assaultive acts are the result. The anxiety state is so common in patients admitted to the hospital for uncomplicated marihuana psychosis that it can be considered part of the intoxication syndrome.

Notes taken on experimental subjects who were psychologically trained² illustrate these points:

The first subject smoked two cigarettes within forty minutes. Immediately after the second a feeling of lightness in the vertex of the head was felt. The head was expanding; there was a feeling of mild excitement. Now the head felt heavy and there was a definite feeling of lengthening in the legs and a tension in the back muscles of the thigh. The head felt alternately light and heavy. There was a sensation as though the top of the head were lifted, with about a 4 inch increase in height, accompanied by optic images of skulls and skeletons. There was a feeling as of the arms rising up in the air. The subject was aware of a feeling of confusion. Suddenly he saw terrifying images of legs and arms in a dissecting room.¹

The second subject smoked two cigarettes. He said: "I feel a little euphoric at first, but with the first draw my heart feels faster and my eyes a little heavier. I feel myself perspiring all over and shaking. I can feel a slight dizziness. I feel weak; the dizziness has left and I am perspiring." (He was asked to walk around the room. He refused to do so and became negativistic.) "On looking back I remembered that I had sexual thoughts during the time of the experiment. Time seemed to pass in a peculiar way, there being a combination of fastness and slowness. I took my first inhalation a few minutes after 9, and when I looked at the clock and saw that it was 10 after 9 I was very much surprised because it seemed like hours. The whole experiment seems now as if it lasted much longer than it did. Walking home I walked slowly in front of oncoming cars and felt a sense of recklessness connected with not being able to walk faster and not caring."

It is remarkable how much anxiety appears when one looks for experimental subjects among the public. The drug is popularly supposed to release aggressive and sexual impulses beyond the point of control; it is also regarded as being habit forming. The history and social connotation of hashish smoking strongly aids in the development of anxieties masking sexual fantasies and aggressive impulses of those who have not taken the drug. This has gone on almost to the point of mass hysteria. Walton has collected a great number of experiences of hashish users among literary and scientific men for the past century. The connotations regarding hashish have been absorbed by both the public and medical observers from these detailed reports, which feature voluptuous, languorous, supernatural and semi-delirious elements following the use of hashish. While such experiences are authentic, it is important for public officials and medically trained observers to realize the literary background from which earlier reports of hashish usage sprang.

In clinical material, as indicated, the effects of marihuana range from mild intoxications to transitory psychoses which require psychiatric aid. The effects vary, and not all the symptoms occur in every case. Case 7 is illustrative of the marihuana psychosis with anxiety reactions and somatic sensory distortions:

CASE 7.—A white man aged 31, admitted March 27, 1934, with a history of having smoked just one cigaret, was depressed, retarded and apprehensive. He was oriented, and his memory showed no defects. Physical examination gave negative results.

He said: "My hand began to feel blue all of a sudden. I felt like laughing and I felt funny in my head. It was the queerest feeling I ever had. I felt like I was kind of fainting away like sweat and then I'd get kind of chilly. I got the scare of my life. I thought I was going to die and everything else. I knew what was happening all the time. I thought my hands were beginning to get blue. My throat began to get kind of dry. It was a little better than getting drunk. I did not want to step down from the curb—it seemed to be so high. I was sitting down and was afraid to get up." The patient improved and on the second day was less apprehensive and was pleasant and cheerful. He was discharged as recovered after two days.

Case 8 demonstrates visual illusions, which recall the megalopsia (the perceiving of objects as larger than they are) and the more common micropsia, which has been reported experimentally and clinically.¹³ It is this type of illusion, induced by hashish, that may have been the basis for the story of Aladdin, who saw the tremendous genii emerge from his lamp spout in the "Arabian Nights" tale:

CASE 8.—A man aged 32, an Irish-American, admitted Sept. 17, 1937, with a history of smoking marihuana cigarettes two hours prior to admission, felt dizzy and wanted to commit suicide by jumping out of windows or bumping his head on the wall or floor. He was uneasy, apprehensive and impulsive. He said "I feel sick. I'm going through hell. I saw trucks coming at me getting larger, and I wanted to open the door of the cab and jump out." He was discharged as improved in his own custody about twelve hours after admission.

13. Drewry,¹² Bouquet.⁹

It is not uncommon to find a history of an admixture of other drugs or alcohol in cannabis intoxication. Frequently alcohol intensifies the symptoms due to cannabis.

CASE 4.—A man of old American stock, aged 27, admitted June 18, 1933, at his own request, had been a chronic alcoholic addict and displayed definite evidences of a psychopathic makeup. He had marked inferiority because of his eyes and body structure. On admission he appeared to be apprehensive and a little excited, but he spoke coherently and relevantly. His experiences were rather clearly set forth: "I was down on the waterfront. A fellow gave me an Egyptian cigaret to smoke. It was of hashish. About an hour afterward I began to see things. I'd see things flying in the air. This made me laugh and I'd laugh at things not worth laughing at. Then I began to see green and other colors flowing before my eyes. Then things got black. I imagined people were following me and I screamed in my hotel and got kicked out. I still see red lines in front of my eyes and other different colors all stuck together. Then I began to hear bells that would get fainter and fainter and then start again. Imagined some one was after me all evening. I thought I heard footsteps and saw people ducking in and out of doorways behind me. At the time I said to myself 'Maybe it will affect my eyes.' I saw a big splotch in front of me—it was scarlet—very bright, exceptionally bright. It contracted, then faded away. I knew all the time it was due to hashish."

2. *Toxic Psychosis.*—Other toxic agents such as alcohol, other drugs and infective or other endogenous elements, may be involved. Disordered sensorium, excitement and agitation, retardation, blocking with

TABLE 1.—Mental Reactions Due to Marihuana

Case	Age	Sex	Race	Use of Cannabis	Diagnosis	Duration	Disposition
					ACUTE INTOXICATION (MARIHUANA PSYCHOSIS)		
1	24	♂	Negro	Once; a few cigarettes	Confused, disoriented, dull and retarded, time disturbance, head "felt like a dream . . . grew bigger"	2 days	Recovered
2	28	♂	Negro	Once; 1 cigaret; chronic alcoholism	Restless and agitated, "queer ideas," death fear, suicidal fear, elation, somatic sensations ("head felt queer, unnaturally big, arms felt big"), sexual stimulation and time disturbance	1 day	Recovered
3	21	♂	Negro	Once; 1 cigaret	Excitement and apprehension, "felt funny, dizzy, thought I was poisoned," visual hallucinations and illusions, sexual stimulation, impulsive wild behavior, euphoria and sense of unreality	Several days	Recovered
4	29	♂	White	Once; 1 cigaret; chronic alcoholism	Visual hallucinations ("see things flying in the air," vivid colors, "different colors stuck together . . . big splotch of scarlet"), euphoria and laughter	7 days	Recovered
5	26	♂	White	Once	Talkative and restless, amnesia for name and family, sexual excitement, homosexual trends, somatic feelings ("I felt heavy in the legs, time went very slowly")	8 days	Recovered
6	29	♂	White	2 years sporadically	Depression with suicidal attempt, scratching of wrists, somatic sensations in trunk and limbs and visual illusions ("houses and people were crooked . . . my body felt distorted like a curved mirror . . . felt like I was flying"), cataleptic postures and later retardation	7 days	Recovered
7	31	♂	White	1 cigaret	Anxiety, depression over physical sensations, "queer feelings," . . . fainting away . . . felt blue . . . sweats and chilliness, fear of impending death, apprehension, later euphoria and laughter	2 days	Recovered
8	32	♂	White	1 day	Apprehensive, suicidal impulses due to sensory illusions and dizziness	1 day	Recovered
9	19	♂	Negro	1 day; alcohol	Stuporous state, confusion and excitement, assaultive tendencies, somatic sensations ("felt funny . . . like walking on air")	1 day	Recovered
10	26	♀	White	1 year; addiction to aminopyrine diethyl barbiturate (peralta); alcoholism	Depression and suicidal tendencies, crying spells and irritability, visual hallucinations ("saw my dead brother")	3 days	Improved
				Readmission 7 months later	Toxic reactions and sexual stimulation, complained of lack of will power to refrain from using alcohol and marihuana, feared enslavement to drugs	2 mos.	State hospital 2 months, discharged improved, psychopathic personality, depression, syphilis
11	19	♂	Negro	4 months; heroin	Depressed and affected by insomnia, personality change, acting queerly, withdrawn, despondent, "disgusted with life"	5 days	Improved, discharged in own custody
12	38	♂	Negro	Few days; alcohol (?)	Confusion and dullness, disorientation, apprehension, disorderly behavior ("ran in street unclothed"), visual illusions ("I see star-shaped figures")	3 days	Recovered
30	20	♂	White	4 months; alcoholism	Excitement and confusion, impulsive suicidal behavior, threatened to kill relative	5 days	Recovered
31	19	♂	Negro	2-3 years, 1 cigaret a day; heroin and alcohol	Confusion, "made me feel like . . . did not seem to walk on ground . . . heard voices"), anxiety over somatic sensations	3 days	Recovered
					TOXIC PSYCHOSIS		
					Subgroup a		
13	23	♀	Negro	"Short time"	Manic-depressive picture, dullness and apathy, later agitation and talkativeness, visual illusions and hallucinations ("I see beautiful colors and designs—red, yellow, blue, green")	4 mos.	State hospital, discharged recovered in 4 months
14	19	♂	White	"Some time"	Depressive features, noisy, irrational, incoherent, auditory and visual hallucinations ("I saw a big ball and father's face in it . . . the buildings were in a circle in the sky"), later depression and apathy	2½ mos.	Improved

TABLE 1.—*Mental Reactions Due to Marihuana—Continued*

Case	Age	Sex	Race	Use of Cannabis	Diagnosis	Duration	Disposition
15	31	♀	Negro	Months	Schizophrenic reaction, early aggressive behavior, visual and auditory hallucinations ("I saw signs in the sky like a person . . . the sun made rays so different, clear and beautiful . . . a kind of changeable color"), later apathy, evasion, persecutory delusions, negativism and emotional rigidity	5 mos.	State hospital, discharged to family, paranoid, schizophrenic
16	16	♂	White	Once (?)	Visual hallucinations ("I see all sorts of colors, yellow mostly . . . just masses. Sometimes a black cross . . . the devil knows evil thoughts in me"), somatic sensations, agitation, fear reaction to hallucinations prominent	3 wks.	Discharged improved
				Readmission 5 months later	Schizophrenia, no marihuana, somatic delusions, religious ideas, guilty feeling over smoking, religious conflicts in foreground, ideas of reference, mannerisms, delusions	3 yrs.	State hospital, condition unchanged, schizophrenia, paranoid type, catatonic features
17	21	♂	White	Prolonged	Emotional excitement, chased people with ice pick, confusion, auditory hallucinations ("voices talk to me, I saw angels, see white lights"), irritable, unsocial attitude	12 days	Improved
				Readmission 2 months later	Schizophrenia, paranoid type, catatonic features	13 mos.	State hospital, paroled, improved
18	20	♂	Negro	5 months steadily; 1-5 a day	Toxic psychosis, paranoid features, euphoria, suicidal impulse, apathy, auditory hallucinations	3 mos.	State hospital, discharged, psychosis due to drugs, recovered
				Readmission after 2 months	Schizophrenia, paranoid type	6 mos.	State hospital, discharged much improved
19	21	♂	Negro	2 years; 2 a day	Toxic psychosis, apprehension, dulness, hallucinations ("people staring at me . . . they spit at me and throw snakes")	5 days	Improved
				Readmission 10 days later	Persecutory delusions, hallucinations, clear sensorium, ideas of reference, schizophrenic picture	6 mos.	State hospital, recovered
20	23	♂	White	More than 2 years, 4-5 a day	Onset with seizure, positive Wassermann reaction of spinal fluid, visual and auditory hallucinations, continued seizures, disturbance of sensorium, depression "I see one big chicken . . . dark colored, I see dragons," cerebral syphilis, toxic psychosis due to marihuana	6 mos.	State hospital, discharged unimproved, schizophrenia, hebephrenic type
21	20	♂	Negro	10 years (?)	Toxic psychosis, schizophrenia (?), elated, excited, euphoric, assaultive, ideas of reference	9 mos.	State hospital, paroled after 9 months
				Readmission 3 months later	Schizophrenia, hebephrenic type	Still in hospital (1938)
27	23	..	Negro	Year or more	Rambling, flighty, elated, at times apprehensive, somatic experience ("my head will bust if I hit it"), confusion and restlessness	5 mos.	State hospital, manic-depressive
					Subgroup b		
22	23	♀	White	7 months; chronic alcoholism	Psychopathic personality with use of marihuana, irritability, violent temper, unmanageable, two suicidal attempts, homosexuality with transvestite tendencies, behavior problem	7 mos.	State hospital, psychosis with psychopathic personality
23	20	♂	Negro	Long period	Personality change, withdrawn, sluggish and lethargic, emotional blunting, sensorium clear, excessive sexual activity, masturbation	10 days	Discharged improved
				Readmitted 1 year later	Toxic psychosis (?), schizophrenia, apathy and dulness predominant, feelings of reference, auditory hallucinations	6 mos.	State hospital, schizophrenia, paranoid type
24	24	♂	White	3-4 years	Manic-depressive psychosis, flighty, grandiose, resistive and irritable, with ideas of persecution, sensorium clear, sexual conflicts and effeminate mannerisms	10 mos.	State hospital, manic-depressive psychosis
				Readmitted 1 year later	Manic-depressive psychosis, two subsequent manic episodes in two years		
25	17	♂	Negro	Short time	Toxic psychosis with schizophrenic features, typical visual and auditory experiences, apprehension and confusion, later seclusive, resistive and mute	4 mos.	State hospital, schizophrenia, hebephrenic type
26	31	♂	White	1½ years, 1 daily	Depressive psychosis with marihuana features, suicidal attempts, dulness and apathy, ideas of reference, visual experiences and auditory hallucinations	3 mos.	State hospital, schizophrenia, hebephrenic type, paroled improved
28	24	♂	White	7	Schizophrenic picture, ideas of influence, auditory and visual hallucinations, emotional dulness, impulsiveness	6 mos., still ill	State hospital, schizophrenia, paranoid type
29	23	♂	White	4 months; alcoholism	Personality changes with schizoid features, ideas of infidelity, assaultive and homicidal threats, suicidal attempts, prolonged psychopathic behavior, paranoid and depressive features	State hospital

emotional rigidity, hallucinations, sensations of somatic change and delusional experiences may appear. The psychosis lasts from weeks to months. Often the mental picture crystallizes into a schizophrenic or manic-depressive psychosis after several weeks or months (table 1). At the onset of the illness what can be considered characteristic cannabis symptoms are discernible. As the underlying functional psychosis develops, the toxic elements recede. Case 16 is illustrative.

CASE 16.—A boy aged 16, admitted Feb. 27, 1934, with a statement from the family that for two months he had been depressed, apprehensive and worried, scratching his hands in a nervous manner, prayed constantly. He complained that somebody read his thoughts. He was well developed and showed no physical signs, but was agitated and depressed and talked constantly in a bizarre manner about the devil influencing him. He said: "I felt light when I was walking—as if I weighed only 10 pounds. I felt like running; my whole body was light. I felt like jumping, as if I was walking on air. I felt happy. Then I saw yellow lights all around me. I saw blue and green too. The colors were more bright than usual. There are just masses of colors—sometimes I see a black cross with everything red behind it. That means there is a God. He is helping me. The devil knows the evil thoughts in me." This agitated condition was alleviated, and the patient was discharged about three weeks

after admission, the diagnosis being a psychosis due to drugs, an acute hallucinatory episode.

The patient was readmitted August 1 with a depression with schizoid features. At this admission there were no evidences whatever of the sensory illusions and somatic feeling that he had had when he smoked marihuana. He was transferred to the state hospital, where he remained four years, his condition being diagnosed as paranoid schizophrenia with catatonic features. There he was restless and overactive. He had a marked push of speech, expressed ideas of reference and religious delusions and was manneristic. He said: "I figured the devil was trying to pull me away from God so I cut a cross on my arm. Physically I am the same, but mentally I am another person . . . I feel that people influence me by touching me—like injecting dope." Later he was manneristic, grimaced, was untidy, repeated practically all questions asked, answered briefly and usually vaguely and would say "I don't know exactly" or "I don't know." He remained dull, apathetic, indifferent and mute.

The personality factor is of undoubted importance in such cases. After the toxic state passed off in those cases in which the intoxication reached deeply enough into the personality, a basic psychotic state developed. At times the toxic features are in the background, the personality reactions being predominant. The inner relationship between cannabis and the onset of a func-

tional psychotic state is not always clear. The inner reaction to somatic sensation seems to be vital. Such reactions consisted of panic states which disappeared as soon as the stimulus (effects of the drug) faded.¹⁴ It is generally known in psychopathology that when the perception of one's own bodily sensations is disturbed one is liable to be profoundly affected psychologically. Disturbances in perception of the body model (*körperschema*), which is built up of kinesthetic, tactile, visual and other stimuli and integrated into the core of the personality, elicit some type of reaction. Such disturbances act as a blow to the ego, invoking defensive reactions of anxiety, apprehension and projection, which approach schizophrenia or are schizophrenic in their clinical manifestations. Case 18 illustrates these points:

CASE 18.—A Negro aged 20, admitted Feb. 22, 1936, was said by his mother to have been "nervous" for some time; he said that he wanted to die, wanted to kill himself. Prior to admission his mother caught him with a bottle of compound solution of cresol. He had been depressed and despondent. He was of superior intelligence as measured by the army alpha test. On admission he stated that he had used marihuana for several months, and during this time he had heard people talking about him. They said: "Oh, what an ugly boy. How mean looking he is." For four months, from August to October 1935, he smoked from three to four cigarets a day, until he began to feel ill. At first marihuana made him happy. Then he felt that he made a peculiar noise in his throat; he ate once a day, was unable to sleep and experienced auditory hallucinations. The hallucinations had started four months before and increased gradually. He thought his face was changing. He looked thin, mean and ugly; he became self conscious. He felt that every one in the neighborhood knew it. He stated that at times he seemed speeded up, but his mind was keenly alert. With the development of the ideas of reference, he became self reproachful, apprehensive and fearful.

He was transferred March 13, 1936, to a state hospital, where he stated that his hallucinations had disappeared and his emotional reaction improved. After three months he was discharged to his home. Within five months he was readmitted to Bellevue Hospital, where he had gone in a state of panic and from where he was recommitted to a state hospital. He was tense and uneasy, retained ideas of reference and acted oddly at home, apparently in response to his delusions. The diagnosis on the second admission to the state hospital was dementia praecox, paranoid type, which was made about two years after the onset of the original illness.

Some patients showed the manic-depressive reactions, but these were in the minority. It is perhaps to be expected that schizophrenic-like psychoses are more common, because persons who take to drugs have some deep inadequacy to start with. The cyclothymic personality is less prone to require drugs:

CASE 27.—A man aged 28, who was brought to the hospital by his mother Feb. 13, 1938, with a history of having smoked reefers for some time, a year before had had an episode, was not hospitalized and improved from it. On admission he was confused, restless and apprehensive. He engaged in violent day dreaming. At times he appeared to be reacting to hallucinations. He said that he "had a big head." He became talkative, euphoric, elated and overactive after a day or so. He said: "The best thing for me to do is . . . you look fine . . . I've got to look like you. . . . I know what it is . . . when a Buick and a Packard get together." His speech was distinctly flighty and his behavior manic; he was constantly restless and would cry, sing and talk.

He was transferred to a state hospital February 24. There his condition persisted and he became somewhat depressed but showed promise of recovery a few months after admission. The diagnosis at the state hospital was manic-depressive psychosis, manic type.

Mixed reactions merged with the toxic psychoses. These reactions varied clinically, some occurring in chronic alcoholic addicts, some in schizophrenic patients and some in persons with psychopathic personalities, and in all of them the use of marihuana was a factor. It can be clearly seen that, aside from the direct toxic effect of the drug, the personality of the patient plays a tremendous part in psychotic states following the use of marihuana:

CASE 26.—A Cuban man aged 34, who was admitted March 6, 1938, to Bellevue Hospital, had jumped in front of a subway train without injury. He was very depressed, dull, lackadaisical and despondent. He was definitely underproductive but still strongly suicidal. He described taking one marihuana cigaret every day for a year and a half because it took his worries away. For some time he had been conscious that people were looking at him. He felt that his body was heavy all the time. Sometimes he heard deceased persons talking to him. He saw lights at times and at times a photograph of a strange person.

A friend corroborated the history, stating that the patient had been in this depressed condition for three or four years. He had a workhouse sentence for from two to three months in connection with marihuana. He was transferred to a state hospital March 18. At that time he was dull and preoccupied but had lost his hallucinatory and delusional trends. The state hospital diagnosed his condition as schizophrenia, hebephrenic type (?), and he was released after two months.

In some cases the drug makes relatively little difference in the content of the psychosis. It is for the clinician to determine how much marihuana influences the clinical picture. In South Africa, where dagga (the equivalent of marihuana) smoking is very widespread, a diagnosis of marihuana psychosis is made in the case of any "toxic psychosis in which there are very good grounds for assuming addiction to dagga smoking." It is felt that there should be more exact criteria, such as that outlined for a diagnosis of marihuana psychosis, by which I mean disorder sensorium, characteristic colored visual hallucinations, time changes and subjective and somatic feelings. One is apt to overestimate the place of marihuana in the causation of a psychotic picture:

CASE 28.—A white man aged 28, admitted Jan. 23, 1938, to Bellevue Hospital, had been in a state hospital in Arizona for three months about two years before and in one in Indiana for nine months four years before. He said: "I was smoking this marihuana weed (at the time of admission to the state hospital in Arizona). I ran around the desert for a time, ran out nights and one day knocked on a door and told a woman I was Dillinger. I tried to see how much water I could walk in. I was just like hypnotized and walking in my sleep. . . . Sometimes I feel like something's controlling me. Sometimes I feel just like I'm talking to somebody with my mouth closed. . . . I just ask them a question with my brain and they answer. Sometimes it's a man, sometimes it's a woman's voice . . . it just works in my temple. I think it's imagination. It's just like a dream. . . . People stare at me. . . . Sometimes I see different colors. I had that years ago—just like a light coming toward me; it's not a light, it's an arc."

His affect was flat, and he was dejected and slow speaking. He showed blocking and evasiveness on sexual experiences and had ideas of reference and persecutory ideas.

He was transferred to a state hospital, where he was preoccupied, underproductive and somewhat dissociated. He stated that he had some sort of seizures that were not really fits but that when he had them if he had a sword he would not mind cutting everybody's head off. He also believed that if anybody got killed near the place where he worked he would be blamed for it. He said that when he looked in bright lights he saw visions like all sorts of different colors, including blues and whites, and these seemed to blind him. A diagnosis was made of dementia praecox, paranoid type, and he is still in the state hospital after five months.

14. Baker-Bates, E. T.: A Case of Cannabis Indica Intoxication, *Lancet* 1: 811 (April 6) 1935.

With psychopathic personalities, those with deep inferiorities, the use of drugs is a method of supporting the ego. Marihuana does not always produce the desirable effect. Apparently it is not strong enough to affect the problems which have involved the deeper layers of the personality. Such persons adopt heroin or morphine very soon after a short experience with marihuana. The experience of drug addicts seen at the Court of General Sessions confirms this. Persons addicted to heroin, morphine, cocaine or opium never return to cannabis. Such persons are admittedly psychopathic, in that they need an increment of drug to make their lives tolerable. In case 29 the use of cannabis represented the attempt of the patient to overcome his sexual inadequacy. In this respect the social psychology surrounding the drug is a factor, since marihuana is popularly supposed to free sexual inhibitions and aggressive tendencies.

CASE 29.—A white man aged 23, admitted to Bellevue Hospital March 31, 1938, felt unworthy and thought that he had a venereal disease. He had ideas of infidelity against his wife and was assaultive. He threw a 4 months old baby across a room. He turned gas jets on. On admission he was rambling, talkative, evasive, depressed and self absorbed and had somatic complaints.

He said: "I was sentenced to the workhouse for four months for smoking marihuana. I knew then I was not satisfying my wife and I thought it might help. A year ago some friends gave me the weed. I smoked several. I felt calm and liked to listen to music—very happy—exhilarating feeling—that's all." In the hospital he was talkative, discussed his problem in detail and showed some depression, which became less. The infidelity ideas and his sexual inadequacies concerned him most. He was transferred to a state hospital with a diagnosis of psychosis with psychopathic personality, cannabis a factor.

Often cannabis intoxication represents a stage in the incipience of a psychosis. The patient in whom a functional psychosis is developing strives to overcome the unconsciously perceived difficulties. In this sense the use of marihuana represents a healthy reactive tendency, even though the mechanism may be unknown to the patient. Case 23 illustrates this problem. A boy who had made a successful adjustment on a moderate level of social attainment began to show schizoid behavior shortly after beginning to use marihuana. The process continued to a psychotic state. What role did the drug play? Could the psychosis have begun without the drug? Was the use of cannabis the patient's attempt to cure his developing psychosis? These are problems needing careful judgment and study and wide clinical experience.

CASE 23.—A Negro aged 20, admitted to Bellevue Hospital Oct. 2, 1936, with a history of having been dull and indifferent for some time, insisted on keeping the windows closed and would not leave the house but denied that he heard voices. He would masturbate openly and made signs with his fingers, and other actions were decidedly peculiar. His mother stated that she caught him smoking a sweet-smelling cigaret with a white man and soon after got a history from his companions that he had been smoking marihuana cigarets for a long time.

Observation in the hospital confirmed his withdrawn, retarded attitude. Psychometric examination disclosed an intelligence quotient of 75, with a rating of borderline to dull normal intelligence. He was preoccupied in the ward; it was difficult to obtain his attention; he was evasive and offered many excuses for closing the window and putting out the lights. About ten days after admission he appeared a little more alert and cheerful. He was discharged in the custody of his mother with a diagnosis of incipient schizophrenia (?) or psychoneurosis, reactive state, Oct. 13, 1936.

He was readmitted a year later, Oct. 15, 1937. At that time his mother gave a statment that since he left the hospital he

had been dull, staying in the house in a "deep study." He seemed to listen but did not say anything. At one time he beat up an old man in the house who, he said, called him names. He had attacked a woman for no apparent reason. He slept day and night. He often looked as though he was in a dream. He had had changed personality reactions for more than a year and for two weeks had been distinctly worse.

On admission he was sluggish, dull and lethargic, spoke in a quiet low voice and showed empty affect but was intact in intellectual functions, memory, comprehension and orientation. He was transferred on October 20 to the state hospital, where he was evasive and dull. He showed no interest in the surroundings and did not mingle with the other patients. He expressed mild ideas of persecution and of electricity and was evasive and suspicious. He said that some people across the street called him bad names and believed that an attempt was made to harm him. "I sometimes have a funny feeling in my legs (electricity)." The diagnostic impression included the possibility of dementia praecox, paranoid type.

Gradually he acquired an interest and became sociable with other patients. At all times he was neat and tidy in personal appearance and habits. He improved after five months and was ready for parole.

CRIMINOLOGIC ASPECTS

The history of the use of cannabis, especially in the Old World, indicates the relation between the drug and violent crime. The English writer Peebles¹⁰ noted the high incidence in India of the use of hashish among the criminal insane. Of 652 cases studied, in 24.6 per cent the cause was found to be hashish. In Asia Minor and in northern Africa, among the Arabs, where the use of cannabis is high, it is conceded by officials that there is a direct relation between the drug and crime. Officials¹⁵ state that dagga (hemp) smokers in South Africa, predominantly natives, steal, lie and tend to moral deterioration. Of the dagga users, 37 per cent were dangerous and 13 per cent destructive to property, according to the history. In the south of this country (New Orleans) the incidence of marihuana addicts among major criminals is admittedly high.⁸ Sporadic reports from elsewhere in the country of murders and assaults due to marihuana appear in the press frequently. It is difficult to evaluate these statements, because of their uncritical nature. The bulletin prepared by the Foreign Policy Association⁸ lists ten cases "culled at random from the files of the U. S. Bureau of Narcotics" of murder and atrocious assault in which marihuana was directly responsible for the crime. Among the ten patients, the second, J. O., was described as having confessed how he murdered a friend and put his body in a trunk while under the influence of marihuana.

J. O. was examined in this clinic; although he was a psychopathic liar and possibly homosexual, there was no indication in the examination or history of the use of any drug. The investigation by the probation department failed to indicate use of the drug marihuana. The deceased, however, was addicted to heroin.

Our observations with respect to marihuana and crime were made in the Court of General Sessions over a period of five and a half years. The material in that court is limited as to residence to New York County, although it must be remembered that the offenders come from many sections of the country and are of many racial types. This is important, because the British investigators have noted in India that cannabis does not bring out the motor excitement or hysterical symptoms in Anglo-Saxon users that occur in natives. There

15. Watt, J. M., and Breyer-Brandwijk, Maria G.: *The Forensic and Sociological Aspects of the Dagga Problem in South Africa*, South African M. J. 10: 573, 1936.

are several other difficulties in collecting reliable material, one being the complete dependence on the history and statements of the prisoners without an opportunity for objective tests or other corroborative check, as in the case of other drugs, e. g. heroin or morphine. During routine interviews of some 17,000 offenders in six and a half years, several hundred have been found who had direct experience with marihuana. Their testimony checks with experimental results and clinical experiences with regard to the symptoms of intoxication, the absence of true addiction and the negative connection with major crime. Especially is this noteworthy among sexual offenders and in cases of assault or murder. The extravagant claims of defense attorneys and the press that crime is caused by addiction to marihuana demands careful scrutiny, at least in this jurisdiction.

Table 2 summarizes the cases studied. Of more than 16,000 prisoners, 200 were convicted on drug charges and found to be users of drugs although convicted of other charges. Cases of possession for sale are handled in the Court of General Sessions, which has jurisdiction over felonies.

TABLE 2.—The Cases of 202 Marihuana Users Convicted Between 1932 and 1937* in the General Sessions and Special Sessions Courts, New York City

Record	General Sessions			Special Sessions	
	Charges: Possession and Sale of Drugs	Other Crimes	Total	Marihuana: Possession and Use	Total

Previous charges including drug charges.....	3	11	14	5	19
Previous charges not including drug charges....	22	8	30	29	59
	46	21	67	135	202

* Prepared by Esther E. Boyd, A.B. research assistant.

* In this period there were 16,854 offenders in the Court of General Sessions (which handles felonies), of whom 200 were drug users, and about 75,000 offenders in the Court of Special Sessions (which handles misdemeanors), of whom 6,000 were drug users.

Of this group of 200, sixty-seven were users of marihuana in some degree whether convicted of the crime of selling marihuana or of another crime. The remaining 133 offenders were users of morphine or heroin. It is vital to note again that the only measure of the use of marihuana is the statement of the offender. Selling or possession does not establish usage or its extent if present. On this score one naturally meets evasion and denial fairly consistently. The most reliable source of information is the persons arrested for other crimes and questioned in the routine course of psychiatric study, who have contact with the underworld.

Of the sixty-seven studied, forty-six were convicted of possession and sale of drugs and twenty-one on other charges. Of the twenty-one convicted of crimes other than the possession and sale of drugs, eight were convicted of burglary, five of grand larceny, three of robbery, two of assault, one each of petit larceny, forgery and first degree murder and none of sexual offenses. Burglary, grand larceny and robbery, then, account for sixteen of the twenty-one. There were but two sex cases involving sexual offenses among the marihuana cases, in both of which sodomy had occurred as a previous offense. In three cases the prisoners were what might be called constant users of marihuana. One had commenced the use of marihuana three years before; another, with a sixteen year record, indicated that mari-

huana had been used for fifteen years; the third referred to his use of marihuana as of "several years' duration." None of the offenders reported any lasting effects from marihuana. Questions as to the habit-forming nature of the drug were all answered in the negative.

In only nine cases of the sixty-seven was the criminal record found to commence with a drug charge, indicating that there was not in those cases a close relationship between drugs and the beginning of a career of crime. One must bear in mind that this can be only a presumptive conclusion, in that the offenders may have used drugs without being arrested and thus coming into official statistics.

Most of the narcotic cases in New York County are heard in the Court of Special Sessions, where misdemeanants are handled and where indictments on charges of the possession of drugs for use are returned. In the Court of Special Sessions in the same six year period, of approximately 75,000 indictments for all crimes, 6,000 resulted in convictions for the possession and use of drugs. Since neither the law, the district attorney nor the police department makes any distinction between the several kinds of narcotics in arraignments or indictments, there were no figures from which to estimate the number of users of marihuana as distinguished from the number of users of other drugs. A system of sampling the 6,000 cases was therefore adopted in order to furnish an approximate estimate of the total number of marihuana users who came into conflict with the law.

In this sampling the records of 1,500 offenders, or 25 per cent of the 6,000, were examined. Of these, 135 were charged in connection with marihuana. From this fact it was estimated that about 540 offenders, or 9 per cent of all drug offenders coming to the Court of Special Sessions in six years, were users of marihuana. In analyzing this sample of 135 cases, it was found that ninety-three offenders had no previous record, the previous charge or charges of eight concerned only drugs, five had records including drug charges and twenty-nine had records not including drug charges. Among those with longer records, that is, from four to seven previous arrests, none showed progression from the use of drugs to other crimes.

As measured by the succession of arrests and convictions in the Court of General Sessions (the only method of estimation), it can be said that drugs generally do not initiate criminal careers. Similarly, in the Court of Special Sessions, only 8 per cent of the offenders had previous charges of using drugs and 3.7 per cent had previous charges of drugs and other petty crimes. In the vast majority of cases in this group of 135, then, the earlier use of marihuana apparently did not predispose to crime, even that of using other drugs. Whether the first offenders charged with the use of marihuana go on to major crime is a matter of speculation. The expectancy of major crimes following the use of cannabis in New York County is small, according to these experiences.

HABITUATION

The problem of habituation to cannabis is of grave importance. It should be remembered that marihuana has been used in conjunction with morphine, heroin or cocaine. Occasionally an astute drug pedler will adulterate marihuana cigarettes with morphine or heroin in order to retain his clientele. Such a situation came to notice at Bellevue Hospital, where a youth was admitted for addiction to heroin acquired in this manner. Hence care must be exercised in evaluating the

question of habituation to marihuana to determine whether one is not dealing with adulterated cannabis.

The medical diagnosis of habituation can depend only on the accepted criteria of acquired tolerance and after-effects on withdrawal of the drug. Users of marihuana examined in the clinic invariably state that an increase in dosage is not necessary to achieve the desired effect as time goes on. The increase in cigaret consumption, if it occurs, is apparently related to how often the smoker wishes to experience the sensations produced. To my knowledge, the effects of withdrawal have never been systematically observed in a controlled environment. It has not been possible to observe satisfactorily marihuana users on their entrance into custody to establish their behavior after cessation of usage. For one thing, the law does not allow questioning of a defendant regarding his charge prior to trial. The fact that offenders brought up on marihuana charges do not request medical treatment on their incarceration (with its cessation of drug supply) argues for the absence of withdrawal symptoms. As is well known, users of morphine and opium become violently ill on being taken into custody and away from the source of their drug and are vociferous in their demands for treatment.

Nevertheless, the wide discrepancies between the reports of some jurisdictions and some physicians and those of the New York jurisdiction in the question of addiction to cannabis deserves thought. In the main, American authorities support the view that marihuana is not a habit-forming drug. Asiatic and European writers are not in accord with this opinion.¹⁶ It is worth recording that, because of difficulty in this court in proving marihuana to be a habit-forming drug (*People v. Williams*),¹⁷ the Law Revision Commission, appointed by the New York State Legislature, was requested to amend the Penal Code, section 1751, to read "narcotic" rather than "habit-forming" drug (March 26, 1938). The most that one can say on the basis of ascertainable facts is that prolonged use of marihuana constitutes a "sensual" addiction, in that the user wishes to experience again and again the ecstatic sensations and feelings which the drug produces. Unlike addiction to morphine, which is biochemically as well as psychologically determined, prolonged use of marihuana is essentially in the service of the hedonistic elements of the personality.

PSYCHIATRY OF OFFENDERS

It would be worth while to study the individual personalities of those offenders who had used the drug. All were given psychiatric examinations; of the sixty-seven, none were found to be psychotic. Three were said to have a neurosis, by which is meant a definite clinical neurosis or underlying anxiety, inferiority reactions and character defects clinically demonstrable. The diagnosis for twelve was psychopathic personality with drug addiction involving use of other drugs, and for one was psychopathic personality of the paranoid type.

The others presented personality difficulties¹⁸ of varying types, being recognized as the aggressive type, emotionally unstable type, maladjusted adolescent type, immature type, egocentric type, submissive type and adynamic type. The remainder showed no personality defects other than the remote effects of a low cultural environment. None were considered mentally defective. The main group were within the limits of average intel-

ligence. The psychologic status of the group was high average intelligence one, average intelligence forty-one, dull normal intelligence twenty-one and borderline intelligence four.

COMMENT

The clinical aspects of marihuana intoxication have been indicated in table 1, and a classification is presented. The marihuana psychoses reported in the American literature¹⁹ vary only quantitatively from those reported elsewhere,²⁰ except that cases have not been reported of dementia as described in the Orient. When the intoxication initiates a functional psychosis or is part of an incipient psychosis, obviously the personality factors and the emotional reaction of the patient to the symptoms are more important than the purely physiologic cerebral effects of cannabis. In other words, every case of marihuana intoxication presents a complex picture which must be studied in the light of the individual case. The important problem of suicidal attempts following the use of marihuana has been indicated in the cases reported to represent the response to attacks of anxiety and panic reaction induced by the drug. Unquestionably marihuana is a dangerous drug from this point of view.

The physiologic psychology involved in use of the drug is of deep interest but will not be entered into here. I²¹ have discussed this elsewhere.

SUMMARY

1. The rise of popular interest in the influence of marihuana on insanity, crime and addiction to drugs during the last ten years in many quarters of America points to the usefulness of a psychiatric review of the problem.

2. In thirty-one cases of insanity following the use of marihuana (marihuana psychosis) observed at the Bellevue Hospital, including eleven reported in 1934, the condition was classified as (1) acute intoxication, lasting from hours to days (fourteen cases), and (2) toxic psychoses, lasting from weeks to months (seventeen cases); often the toxic picture was superimposed on a basic functional mental disturbance, such as schizophrenia.

3. Marihuana is a contraband preparation of the hemp plant (*Cannabis sativa*) which contains the active principle cannabis. The common use is in cigarets. Smoking produces characteristic symptoms. It affects the emotional sphere, inducing euphoria and less commonly anxiety and apprehension, and the subjective world, involving feelings of unreality and aberration of the time sense. It induces feelings of bodily change, such as lengthening of the limbs and swelling of the head; it influences the motility, causing restlessness and excitement in varying degrees in different persons, and it produces mental confusion with possible visual illusions and hallucinations.

The basic personality of the smoker appears to be a vital factor in the development of a marihuana psychosis. Countless persons use marihuana without the development of an observable mental condition. Occasionally use of the drug represents the incipient stage of a functional psychosis. In such cases there appears to be an intimate relation between the dissociation in the patient's personality and the subjective effects of the drug, which tend to widen the dissociation and produce a psychosis. In the acute intoxication, no perma-

nent effect is observable by psychiatric examination after the effects wear off in from one to three days.

5. In sixty-seven cases involving marihuana from the Court of General Sessions, New York County, it was found in general that early use of the drug apparently did not predispose to crime. No positive relation could be found between violent crime and the use of marihuana in the cases observed in the Psychiatric Clinic. No cases of murder or sexual crimes due to marihuana were established.

6. The reported lack of increased tolerance and the absence of demonstrable withdrawal symptoms argues against the theory that marihuana is habit forming. The final solution of the problem of addiction waits on further experience and controlled experiment. The present study allows at this time only the statement that the use of marihuana is a "sensual addiction" in the service of the hedonistic elements of the personality.

QUININE AND DYSTONIA MUSCULORUM DEFORMANS

GEORGE B. HASSIN, M.D.

Professor of Neurology, University of Illinois College of Medicine;
Attending Neurologist, Cook County Hospital

CHICAGO

Dystonia musculorum deformans is characterized by excessive, involuntary, uncontrollable movements, some of which are choreiform and others athetoid, cerebellar-like or parkinsonian. It is a purely motor disturbance due, as Oppenheim¹ emphasized, to a combination of motor restlessness with muscular hypertonia and hypotonia. The clinical picture may for a long time be dominated by disturbances of posture and gait (the myostatic phase of Wechsler and Brock²) before muscular restlessness becomes evident. Such cases do not even suggest dystonia and therefore are usually labeled hysteria, chorea, athetosis or some other form of muscular restlessness. Because dystonia resembles some other clinical manifestations, there is a tendency to discard it as a clinical entity.

According to others, dystonia not only is a clinical entity but exhibits definite pathologic changes in some basal ganglions—caudate nucleus and putamen (corpus striatum). Neither of the foregoing views is correct, for, while dystonia is unquestionably a definite morbid entity, it is by no means established that it is an organic disease process. An analysis, for instance, of histologic changes in a typical case of dystonia of only several months' duration in a child justified the conclusion³ that in this morbid condition the corpus striatum is not more involved than any other portion of the central nervous system; that such changes as were found in this case may occur in many other lesions of the central nerve system—degenerative, inflammatory or those caused by exhaustion. On the whole, the histologic changes in my case were not commensurate with the extent and severity of the clinical manifestations and may be considered the result rather than the cause of the hyperactivity of the neuromuscular apparatus. In

short, the neurohistologic changes that have been described in a few cases of dystonia musculorum deformans are probably secondary or accidental, the motor restlessness being most likely caused not by morphologic but by physicochemical factors. These are probably similar to those which are at play in myotonia congenita (Thomsen's disease), in which the anomalies of the muscle tone—myotonic contractions—also are characteristic clinical features. Since the myotonic anomalies in Thomsen's disease can be favorably influenced by quinine, as they were first shown to be by Wolf,⁴ it is only logical to expect an equally favorable effect from this substance on the anomalous muscular contractions in dystonia musculorum deformans, which, as has been emphasized, was justly considered by Oppenheim a disturbance of the muscle tone. The correctness of such an assumption was borne out by the following observations:

CASE 1.—History.—A Jewish girl aged 8 years, whose father was born in Poland and mother in Russia, had had difficulty in using her right foot since the age of 16 months. From this age on the child had walked on her toes, which when at rest would droop off and on, though she could move the foot in every direction. In walking, the patient dragged the right lower extremity; the gait was "jumpy, limping or dancing-like." At the age of 4 years the patient commenced to feel tired in the afternoon and would become "stiff." In the morning she would feel well. She was able to attend school, run and, in general, behave like a normal child. Three years later twitching occurred in the neck and all the extremities. The condition grew progressively worse in spite of various methods of treatment. The child, for instance, had been kept in a large hospital for five and a half months in a cast "from the waist down," and after the cast was removed the patient was unable to walk at all. Several months later, about a year before she was seen by me, she commenced to have "attacks" during which, while entirely conscious, she would become rigid and her head would droop over the chest and, like the extremities, exhibit spasmodic movements. In sleep the restlessness ceased. The two younger children (twins) were not affected by similar disturbances.

The parents were healthy and free from any mental or nervous anomalies, and the patient herself had had no other physical or nervous ailments.

Examination.—The patient was brought to my office March 8, 1938, in the afternoon, when, according to the parents, she always felt worse. The child was carried by her father, for she could not stand, walk or sit up because of violent grotesque twisting movements of the neck, trunk and upper and lower extremities. The patient's body was doubled up; the head was drawn over the chest and was in constant lateral motion; the legs were rigidly extended. When seated, the patient would assume a squatting posture, the feet inverted and the head supported by the hands. She was unable to relax her spastic extremities, which would become more spastic from attempts to change their position. The extreme restlessness that accompanied such attempts was associated with heavy breathing, palpitation of the heart, flushed face and profuse perspiration. The only position that afforded some relief during the attacks was lying on the abdomen or a so-called genupectoral posture, the knees flexed, the body bent and the head resting on the hands. An attempt to change such a posture would renew the restlessness. The patient's mental condition and cooperation were excellent. The cranial nerves, speech and sensibility were normal; the tendon reflexes were lively throughout; the Babinski sign was elicited only occasionally; atrophies, hypertrophies and deformities such as lordosis, genito-urinary anomalies and pupillary or fundus changes were absent.

I ordered 1 grain (0.065 Gm.) of quinine sulfate chocolate covered tablets, three times a day; the dose was to be increased

From the Department of Neurology and Neurological Surgery, University of Illinois College of Medicine, and the Cook County Hospital.

to 5 grains (0.32 Gm.) three times a day. Unfortunately, the child's mother had lost faith in any kind of treatment, especially after her experience with the "cast from the waist down" and for two weeks the patient was given 1 grain of quinine a day. Some improvement was noticed even from the small doses, and these were increased to 5 grains three and afterward four and even five times a day. The improvement was striking. When seen by me for the second time June 15 there were no twitching, distortions, tremors or genupectoral postures. The child was able to handle objects and could write without difficulty. The letters were well formed and showed no signs of tremor. The reflexes were hyperactive as before, but the Babinski sign was not elicited. When she walked the feet, especially the right foot, assumed an equinovarus position; they would become slightly inverted and were dragged. At rest, especially when she was on her back, the spasticity would be replaced by muscular relaxation; coordination was normal in both upper and lower extremities, which exhibited good muscle power and no tremor. Whenever quinine was discontinued, slight muscular restlessness would reappear; but it was possible to reduce the dose of quinine to 5 grains twice a day and even to discontinue it for several days with no apparent discomfort to the patient.

Jan. 30, 1939, the condition was still very satisfactory except for the gait, which still was laborious, for the most part in the afternoon, when, as before the treatment, the patient was feeling tired, but she would become refreshed after a short rest of half an hour.

Aside from the improvement brought on by the quinine therapy, this case is remarkable also for other features: the unusually early onset of the dystonia, which set in at the age of 16 months, the earliest previously on record being the cases of Navarro and Marotta⁵ (onset at 2 years) and of Fritz⁶ (onset at 3 years); the onset with postural anomalies which for almost six years were the only manifestation of the disease and which persisted despite the remarkable improvement in the muscular restlessness or myokinetic features, as Wechsler and Brock designated this phase of dystonia.

The reverse picture (improvement in the postural phenomena) was observed in the next case. The patient was an adult, and the duration of the disease was much longer before the treatment with quinine was instituted.

CASE 2.—History.—A white unmarried woman aged 43, born in this country of Bohemian parents, was admitted to the outpatient neurologic clinic of the Research Hospital March 23, 1938, because of "nervousness" and twitchings, of about ten years' duration. The patient's sister and two brothers are living and well; the father died in an accident at 45. There was no similar condition in the family.

The patient was well nourished and cooperative and stated that she had been in good health until ten years previously, when her left hand commenced to shake. No involuntary movements were present at rest but on attempts to move the affected hand it would be seized with a tremor, so that the patient was unable to handle objects. The condition progressed, and within a year the neck and the other hand became involved. The head would turn toward the left and the chin would be drawn to the right, the contractions being associated with involuntary muscular movements in the arms and legs. The condition grew in severity and the patient had to give up her work (that of a clerk) since she was unable not only to handle objects but also to walk unsupported.

About five years after the onset of the foregoing complaints the patient occasionally experienced diplopia and some difficulty in articulation. Six months before admission she commenced to experience pain in the left lower extremity "from the hip down to the left leg."

Examination.—When the patient was admitted to the Research Hospital May 17, 1938, she exhibited marked involuntary muscular contractions throughout the body—in the neck,

trunk and upper and lower extremities. There were marked slow, muscular contractions in the upper extremities and a tremor in the hands which increased on exertion, while the movements in the head were in the form of slow contractions which caused the head to turn to the left. The gait was slow, "deliberate" and in small steps, and the patient had to be supported because she often "stumbled."

The reflexes were hyperactive (4 + for the knees and the biceps) but the Babinski sign was absent. The motor power was fair in the upper but poor in the lower extremities. The cranial nerves, sensibility, pupils and fundi and serologic reactions were all normal. The speech was normal; only once was mention made in the records of a slight disturbance in articulation. While in the hospital the patient complained a great deal of pain in the hip, which was relieved by an epidural injection. For the dystonia quinine sulfate was prescribed in 5 grain doses three times a day. The improvement was gradual and by June, about three weeks after her admission to the hospital, the patient's gait had improved so much that she walked without support and did not stumble. The twitchings in the head and extremities, however, showed no change nor could the patient handle objects, which dropped from her hands. The dosage of quinine had to be reduced to 1 grain three times a day because of cinchonism, but one thirtieth grain (0.002 Gm.) of arsenic trioxide was added. In spite of the reduced dosage of quinine the shaking in the hands also showed improvement, Aug. 26, 1938. During October, November and December the patient had not been taking quinine, yet there was no tremor. The doses of quinine were increased to 5 grains three times a day. Improvement was so great that the patient was able to do housework without discomfort or dropping dishes. In the neck, twitchings were absent at rest and would be brought on only by excitement.

The "diplopia" and pain in the left lower extremity evidently had no relationship to the involuntary muscular contractions, for they both set in long after the onset of the dystonia, the pain probably having been due, as the roentgenogram showed, to an osteo-arthritis. The diplopia was only occasional and had not been complained of during the last four years.

Equally favorable was the action of quinine in a case of dystonia which ran as spasmodic torticollis:

CASE 3.—A white woman aged 43 was admitted to a medical ward of the Cook County Hospital Dec. 12, 1938, because of spasmodic contractions of the muscles of the neck. Three months prior to entrance to the hospital the patient lost her home and job (that of a house detective), and a week later twitchings in the neck developed which would draw the head to the left and backward. The twitchings would occur in spells, three or four times a day, and would last about five minutes. Bromides and phenobarbital gave no relief, and ten days later the patient was transferred to the neurologic service, where she was given 10 grains (0.65 Gm.) of quinine sulfate and hydrochloric acid three times a day. Already within four days there was evident improvement, and about a week later (December 30) a note in the nurses' record reads: "feels grand and holds up head quite well." When the medicine was discontinued the twitchings reappeared, though they were less intense. Valerianates and electrical treatment were substituted and also gave relief, but the results were by no means as favorable as from quinine. The patient was practically well at the time of the last observation (Feb. 14, 1939).

Without going into a discussion on the nature of spasmodic torticollis, justly considered by some a partial manifestation of dystonia musculorum deformans,⁷ it should be emphasized that it is a most stubborn type of an involuntary muscular contraction. It is considered by the majority an organic disease and by others a functional nerve disorder; hence the name mental torticollis given to it by Brissaud. Such cases are not uncommon and, as shown elsewhere,⁷ patients are usually treated, often successfully, by surgical methods. It is suggested to try treatment of such cases with large

doses of quinine (at least 30 grains [2 Gm.] a day), which are also recommended by Lonergan and Paskind⁸ in the treatment of myotonia congenita.

CONCLUSIONS

The muscular restlessness in dystonia musculorum deformans is, as in Thomsen's disease (myotonia congenita), probably a disturbance of the muscle tone.

Like myotonia congenita, dystonia markedly improves with quinine therapy.

Large doses should be given if possible; they are of decided benefit even in cases of so-called spasmodic torticollis, which is also known as torsion spasm (a partial manifestation of dystonia).

SULFANILAMIDE FOR PUERPERAL INFECTIONS DUE TO CLOSTRIDIUM WELCHII

JOSEPH F. SADUSK JR., M.D.

AND

CONSTANTINO P. MANAHAN, M.D.

BALTIMORE

Since the original report of Dobbin,¹ from this clinic in 1897, *Clostridium welchii* infections in the puerperium have been described by many observers. The literature up to 1928 has been adequately reviewed by Toombs and Michelson,² and since then significant communications have been added.³

Cl. welchii, known commonly also as *Bacillus aerogenes capsulatus* and the gas bacillus, is a rather short gram-positive rod, nonmotile and growing under fairly strict anaerobic conditions. It forms capsules in the animal body and under certain conditions readily sporulates. A so-called stormy fermentation of milk, with formation of clot, acid and gas, is characteristic. Classification into four types—A, B, C and D—is recognized, but only type A is met with in the human body. The organism is found in soil, water, milk, dust, sewage and the intestinal canal of man and animals. Its occurrence normally in the human vagina is debated, but investigation under way at the present time in this clinic lends support to the view that the Welch bacillus may be found in the lower portion of the human vagina in a certain number of cases and will be reported in a later paper. Hemotoxin and myotoxin are produced, accounting for certain characteristic clinical observations. Antitoxic serum is readily prepared by means of horses.

The symptoms found in puerperal infection due to this organism are those of an exceedingly acute and fulminating infection. Severe abdominal pain, vomiting and chills are invariably present. The temperature is usually elevated, there is marked tachycardia and prostration is extreme, with hypotension. It is characteristic that patients dying with this infection are usually mentally clear up to the time of death. Jaundice and a deep

malogany cyanosis due to destruction of the red blood cells by hemolysins are occasionally seen and may develop with great rapidity. The mortality is then practically 100 per cent. It is important to note that evidence of gas formation in the tissues, which is so commonly seen in surgical conditions, is found infrequently in obstetric infections due to this organism, even up to the time of death.

Puerperal infection with *Cl. welchii* is more common in postabortal conditions than in puerperal infections following the birth of a viable child. Figures given in the literature indicate that from 60 to 75 per cent of these infections are postabortal.

The mortality is extremely high. In reviewing the literature⁴ available to us, we found a mortality of 85 per cent for patients receiving no specific therapy and of 47 per cent for patients treated with specific antiserum.

The use of high voltage roentgen therapy has been advocated by Kelly and Dowell⁵ in the treatment of surgical gas bacillus infections. Recently Bohlman⁶ and Kennedy⁷ have reported the successful use of sulfanilamide for surgical infections, but as yet no statements are on record concerning the use of this drug for obstetric infections due to *Cl. welchii*.

It is the purpose of this communication to report (1) the treatment with sulfanilamide of two severe postabortal infections due to *Cl. welchii*, both with positive blood cultures, and (2) to offer experimental data concerning the effect of sulfanilamide in vitro on this organism.

REPORT OF CASES

CASE 1.—*History and Course*.—A. H., a white woman aged 27, a housewife, had been delivered spontaneously of a normal full term child in 1934. Her last menstrual period began Nov. 17, 1938. She was admitted to the medical service of the Johns Hopkins Hospital Jan. 6, 1939, because of long-standing hypochromic microcytic anemia, the result, presumably, of chronic bleeding from intestinal varices. Termination of pregnancy was advised because of this condition.

Accordingly she was transferred to the obstetric service the morning of February 23, at which time the first stage of a therapeutic abortion was carried out. The uterus was found to be enlarged to the size of a twelve weeks pregnancy. The cervix was readily dilated by means of Hegar dilators, and the lower uterine cavity and cervical canal were tightly packed with dry gauze. Shortly after 8 a. m. the following day (February 24) the patient had a slight chill and her temperature rose to 101.8 F. She complained of severe pain in the lower part of the abdomen. At 9 a. m. the second stage of the therapeutic abortion was carried out. The cervix was dilated readily with Hegar dilators, and, after culture of the uterine contents, the products of conception were removed with ovum forceps. No curettage was attempted. During this procedure the pulse rate rose to 160 and the temperature to 105 F. Blood for culture was taken at this time.

At 8 p. m. of the same day, eleven hours after the operative procedure, both blood and uterine material taken in the morning for culture were found to be positive for *Cl. welchii*. The blood culture contained one colony per 2 cc. of blood, and the uterine culture, in addition to a moderate growth of *Cl. welchii*, showed the presence of yeast belonging to the genus *Saccharomyces* in heavy growth. The patient was now critically ill and was extremely prostrated. She was cyanotic, breathed shallowly and responded poorly. The abdomen was greatly distended and

exquisitely tender everywhere to even the lightest palpation, so that the uterus itself could not be felt. Blood for another culture was taken at this time (subsequently yielding two colonies of *Cl. welchii* per 2 cc. of blood) and the oral administration of sulfanilamide begun in equally divided doses every four hours, as illustrated in chart 1. The following morning the patient was still critically ill and cyanotic, but by 8 p. m. of the same day (February 25) her condition showed marked improvement, despite the continued fever. She was brighter and responded well. Abdominal tenderness and distention had disappeared to a great extent, and the uterus, which itself was quite tender, was palpated a fingerbreadth below the level of the umbilicus. The lochia was moderately foul and profuse. Blood for culture taken at this time remained sterile.

On the morning of February 26 the improvement continued to be dramatic. There was no abdominal tenderness, and, though she was somewhat lethargic because of the sulfanilamide, her response to stimuli was excellent. Further blood cultures remained sterile. Daily determinations of the sulfanilamide in the blood were done, the level reaching 12.2 mg. per hundred cubic centimeters, as recorded in chart 1. Further vaginal cultures, of material taken February 28 and March 2, showed the continued presence of the *Welch* bacillus in addition to anaerobic nonhemolytic streptococci.

Additional laboratory data showed no change in the non-protein nitrogen content or carbon dioxide-combining power of the blood during the course of therapy, 5.4 Gm. of sodium bicarbonate having been given daily in order to prevent acidosis. The icterus index of the blood serum remained within normal limits throughout, but urobilin was excreted in the urine in not inconsiderable amounts during the early part of her illness.

It is of interest to note that despite the intensive sulfanilamide therapy, a drop of only 1.7 Gm. (11 per cent) in the blood hemoglobin content took place.

The patient was discharged to the medical wards March 7 in excellent condition. Details of her course during the period of active therapy are shown in chart 1.

Bacteriology.—The organism isolated from the blood and from the intra-uterine material were identical. It was a gram-positive rod, growing luxuriantly in cooked meat mediums with the production of large amounts of a sour-smelling gas which

the lesion revealed numerous encapsulated gram-positive rods. Culture of the heart's blood contained 31,000 colonies of *Cl. welchii* per 1 cc. of blood.

Pathology.—Microscopic examination of the placenta removed at operation showed a moderate amount of leukocytic infiltration between the chorion and amnion, which were well preserved. In this region, especially where the leukocytic infiltration was

Chart 2 (case 2).—Clinical and laboratory data.

heaviest, numerous gram-positive rods were found. No evidence of infection of the chorionic villi themselves could be found.

CASE 2.—C. J., a housewife aged 27, white, had had five previous full term pregnancies and three spontaneous abortions. Her last menstrual period began June 11, 1937. She was admitted to the obstetric service of Johns Hopkins Hospital September 17 with the story of spontaneous rupture of the membranes and vaginal bleeding several hours before. She denied any attempt at interference, but told that an unsterile vaginal examination had been done by her physician shortly after the onset of bleeding. Some time after this she was seized with chills, fever and malaise. Examination revealed an enlarged, slightly tender uterus, moderate vaginal bleeding, a temperature of 101.4 F. and a pulse rate of 110. Six hours after admission she spontaneously aborted a 20 cm. fetus.

The patient had a severe shaking chill the next morning, after which the temperature rose to 105.8 F. Examination then revealed rather marked tenderness in the lower part of the abdomen as well as rigidity in both lower quadrants. The administration of sulfanilamide was begun, as illustrated in chart 2, but was discontinued at the end of the day, when the temperature had fallen to normal. However, when the blood which had been taken for culture at the time of the shaking chill was shown to be positive for *Cl. welchii* and the temperature began to rise again, the administration of sulfanilamide was resumed. Blood culture at this time was sterile, but intra-uterine culture revealed the presence of *Cl. welchii*. The patient's clinical course and fever readily responded to this therapy. Details are given in chart 2.

In this case, identification of the organism was limited to morphologic examination and observation of growth in cooked meat mediums under petrolatum seal and the production of stormy fermentation in milk. The blood culture, unfortunately, was not quantitated.

COMMENT

In both the cases reported, sulfanilamide seems to have exerted a therapeutic action. This is especially striking in view of the extremely high mortality of obstetric infections due to the gas bacillus, as we have already noted. In Peckham's⁸ analysis of deaths due to puerperal infection, whereas *Cl. welchii* was found in only 0.65 per cent of intra-uterine cultures taken as

8. Peckham, C. H.: Statistical Studies on Puerperal Infection: Analysis of 115 Deaths Due to Puerperal Infection, *Am. J. Obst. & Gynec.* 31: 996-1003 (June) 1936.

Chart 1 (case 1).—Clinical and laboratory data.

exploded when ignited. Motility was absent. Characteristic stormy fermentation of milk was produced readily. Gelatin was completely liquefied. The organism grew only under anaerobic conditions on defibrinated rabbit's blood agar plates, producing areas of complete hemolysis surrounded by a secondary area of incomplete hemolysis. This "double zone" hemolysis was observed even to better advantage in deep blood agar pour plates. A powerful soluble hemolysin for rabbit's blood was demonstrated. As little as 0.1 cc. of a twelve hour cooked meat broth culture injected intramuscularly into a 450 Gm. guinea pig produced death in thirty-one hours. Autopsy showed extensive necrosis at the point of injection, and a smear from

a routine in cases of fever, this organism was found in 15.38 per cent of the cases of fatal puerperal infection. Hill³ stated that 33.3 per cent of deaths due to abortion in the city of Melbourne, Australia, during the year 1934 were due to infection with the gas bacillus and that in his own clinic 48 per cent of abortion deaths were due to this organism. This figure is based on 1,565 abortions occurring in one year.

In the second case presented, the bacteremia may have been transient and, moreover, the organism was not identified as accurately as one might desire, since there are said to be several species of motile anaerobic bacilli which produce the so-called stormy fermentation in milk.⁹ In the first case, however, there remains no question of the identification of the organism and demonstration of its virulence by animal inoculation. With two positive cultures of blood taken eleven hours apart,

the patient's clinical appearance before administration of the drug and the dramatic response to the therapy, there can remain little doubt as to the specific action of sulfanilamide in this case.

The early diagnosis and immediate therapy of gas bacillus infections must be stressed, in view of the fulminating character of these infections. Toombs and Michelson's² review of the literature revealed that one third of the patients die within forty-eight hours of the onset of infection, and Dawbarn and Williams¹⁰ reported a case of abortion in which the patient died nineteen hours after the first appearance of symptoms. In our first case, a diagnosis of severe intra-uterine infection with bacteremia was made twelve hours after the onset of infection, and introduction of therapy at this early period doubtless accounts for our success.

In cases of severe infection, with signs of marked toxicity, in which an early diagnosis has not been made, it would seem logical to administer both sulfanilamide and specific antiserum in massive doses, the latter for the purpose of neutralizing the toxins formed and the former in order to control the local lesion and the

bacteremia. Sulfanilamide should be given in massive doses during the stage of bacteremia, at least 6 or 8 Gm. a day, divided into equal doses given every four hours throughout the twenty-four hour period. The concentration of sulfanilamide in the blood should be followed daily, and the usual precautions should be taken to determine the onset of toxic reactions as early as possible.¹¹ It is wise to administer sodium bicarbonate orally, in doses of from 4 to 8 Gm. a day, in order to prevent the development of acidosis.¹²

STUDY OF IN VITRO EFFECT OF SULFANILAMIDE ON *CLOSTRIDIUM WELCHII*

Bliss and Long¹³ have studied the use of sulfanilamide in the treatment of experimental *Cl. welchii* infections in mice and in addition have observed a definite in vitro¹⁴ effect on the organism. They found that the beneficial results obtained were due not to a bactericidal action of the drug on the organism but rather to a bacteriostatic action. Studies of the peritoneal exudate from infected mice indicated that sulfanilamide inhibited the growth and multiplication of the bacteria, thus allowing phagocytosis to control the infection effectively. On the other hand, Spray¹⁵ has recently challenged any bacteriostatic activity of sulfanilamide on *Cl. welchii* in vitro. In view of this disagreement, we carried out a number of experiments testing the in vitro effect of varying concentrations of sulfanilamide.

The organism used in this work was that isolated in case 1. To sterile test tubes, each containing about 1 Gm. of sterile sand in the bottom of the tube, was added 10 cc. of freshly boiled beef infusion broth (pH 7.6) containing 1 per cent dextrose solution and varying concentrations of sulfanilamide (the latter added after boiling the broth). The broth in the tubes was then capped with a 1 cm. layer of melted sterile petrolatum and the whole heated again in a boiling water bath to insure the absence of dissolved air. After the contents of the tube were cooled to room temperature and the petrolatum seal opened the inoculum was added in 0.1 cc. quantities to the bottom of the tube and the contents were sealed again with petrolatum. The contents of the tubes were thoroughly mixed by agitation of the sand after the seal had solidified. Incubation at 37.5 C. was carried out, and observations were made repeatedly on the presence of growth and gas.

In the accompanying table is a summary of the results obtained after incubation periods of twenty and forty hours, respectively. Quantitative estimations of the inoculums were carried out by means of colony counts from serial dilutions of a twenty-four hour cooked meat broth culture plated out in anaerobic blood agar plates. Dilution of the cooked meat broth culture was carried out to the necessary degree in order that 0.1 cc. of the dilution might contain the number of organisms desired. It should be stated that the quantitative counts of the inoculums were of course not known until twenty-four hours after the beginning of each experiment. The degree of turbidity and the amount of gas formation are represented in the table by values from 1 to 4+, as determined by visual inspection.

15. Spray, R. S.: Bacteriostatic Action of Prontosil Soluble, Sulfanilamide and Disulfanilamide on Sporulating Anaerobes Commonly Associated with Gaseous Gangrene, *J. Lab. & Clin. Med.* 22: 609-614 (March) 1938.

9. Society of American Bacteriologists: Manual of Methods for Pure Culture Study of Bacteria (Committee on Bacteriological Technique), 1936, and The Study of Obligately Anaerobic Bacteria, ed. 3, 1937; Geneva, N. Y., Society of American Bacteriologists.

10. Dawbarn, R. Y., and Williams, Bryan: Three Cases of *Cl. Welchii* Infection Following Abortion, *Brit. M. J.* 2: 279-281 (Aug. 6) 1938.

The data supplied in the table indicate that sulfanilamide exerts a definite inhibiting reaction on the growth of *Cl. welchii* and, moreover, that this bacteriostatic action is inversely proportional to the number of organisms used as the inoculum. That a bactericidal effect was not obtained, however, is readily shown by the fact that in those instances in which growth did not take place in the mediums containing sulfanilamide, definite growth resulted if a portion of this was transferred after forty hours to sulfanilamide-free mediums.

The growth obtained was ordinarily diffuse, but in the higher sulfanilamide concentrations a flocculent precipitate was obtained at the bottom of the tube with a clear supernatant broth, not unlike the condition sometimes observed when certain organisms are grown in dilutions of their homologous serum.

It seems reasonable to suppose, with the data supplied, that Spray's failure to obtain satisfactory results with sulfanilamide was due to the heavy inoculation of *Cl. welchii* used in his experiments.

SUMMARY AND CONCLUSIONS

1. In two cases of postabortal *Cl. welchii* infection with positive blood cultures the blood stream was rapidly sterilized by the use of sulfanilamide and the patient recovered.

2. Experiments demonstrated the bacteriostatic action of sulfanilamide on *Cl. welchii* in vitro. Such action is inversely proportional to the number of organisms used as the inoculum.

THE PROLONGED USE OF PROTAMINE ZINC INSULIN

HERMAN O. MOSENTHAL, M.D.

AND

MORTON F. MARK, M.D.

NEW YORK

The immediate results of the use of protamine zinc insulin in diabetes have been frequently discussed. The effect of the prolonged use of protamine zinc insulin has not been so carefully considered. Ralli and her co-workers¹ gave a discouraging account of their experience with twenty patients at Bellevue Hospital. Graham² believes that protamine zinc insulin "will be the most popular method and will prove to be the best for the easy cases," though he cautions against premature enthusiasm until more experience has been obtained with it. McCullagh³ found that sixty cases of diabetes responded exceedingly well to the prolonged use of protamine zinc insulin; Priscilla White⁴ reported remarkable success in children: "95.0 per cent (574 patients) were known to be taking either protamine zinc insulin alone or in combination with regular insulin." Boyd and Jackson⁵ obtained indifferent results in children, which they explained by the more rigid standards, especially in regard to the blood sugar, that they insisted on for their patients; Rabinovitz⁶

lends a refreshing note to the situation in a plain statement: "We have very little trouble in using protamine insulin and believe it to be of great advantage. . . . We have had a few cases in which it was necessary to revert entirely to regular insulin." It becomes apparent that the opinions pro and con about the value of protamine zinc insulin are not unanimous, and this has prompted us to analyze the causes for success or failure in our cases.

The status of diabetic patients after six months or more of treatment with protamine zinc insulin is presented; when protamine insulin had been used some time previously this period is included in stating the duration of treatment with protamine zinc insulin. A comparison of the disease between the period when regular insulin was used and when protamine zinc insulin was used is given when the data are available.

CLINICAL MATERIAL

The clinical material was derived from three sources: (1) private patients controlled almost entirely by office visits (designated as office cases); (2) ambulant patients treated in the outpatient department of the New York Post-Graduate Hospital (designated as dispensary cases); (3) hospitalized patients at Sea View Hospital, a large institution devoted to the treatment of tuberculosis (designated as hospital cases). This material represents a cross section of the well-to-do, persons with moderate incomes and the indigent. The indigent patients were treated at Sea View Hospital and, consequently, were not in their natural environment and therefore cannot be regarded as comparable to the cases reported by Ralli and her associates.¹ About two thirds of these patients (office and dispensary cases) were ambulant and treated only at intervals, while about one third of them were hospitalized and had closer supervision (tuberculous cases at Sea View Hospital). In our experience, the presence of a complicating tuberculosis affected the clinical picture of the diabetes but little or not at all unless the patients had considerable or prolonged fever or were moribund; data on such persons are not included; there was a total of 114 cases, made up of forty-five hospitalized cases, forty-one office cases and twenty-eight dispensary cases.

STANDARD OF CONTROL IN DIABETES

The criteria by which the success or failure of the treatment of diabetes may be evaluated should be mentioned so that it is clearly understood what standards are used in this presentation to judge of the adequacy of protamine zinc insulin. The aims of treatment vary from time to time according to prevailing theories and to the development of new facts, so that any exposition of this sort is necessarily controversial and portrays only transient truths.

The yardsticks by which the control of diabetes is judged are the level of the blood sugar and the presence or absence of sugar in the urine.

Some clinicians and students of the subject believe that the blood sugar must be maintained at physiologic levels for the utmost results,⁷ while others⁸ consider that

hyperglycemia without glycosuria is not only harmless but may be of benefit in diabetes, especially in elderly persons.

The occurrence of occasional moderate glycosuria is usually considered harmless to the patient and very often unavoidable. John⁹ regards 10 Gm. of sugar in the urine in twenty-four hours as the upper desirable limit. The situation is satisfactorily summarized by Gray:¹⁰ "Children seem to grow at a normal rate,

TABLE 1.—Summary of the Results of Treatment with Protamine Zinc Insulin or Protamine Zinc Combined with Regular Insulin for Six Months or Longer

pass successfully through accidents and illnesses, avoid the classic complications of diabetes and lead happy and useful lives in spite of never being exactly sugar free." It is our belief that glycosuria should be avoided but that sugar in the urine on occasion does no harm and is preferable to hypoglycemic reactions, though we do not endorse the idea recently expressed in an editorial¹¹ that huge quantities of sugar in the urine over periods of years do not cause damage. Himwich⁸ has carefully analyzed the reasons why such practice is indefensible.

With these facts in mind we have designated as good results with protamine zinc insulin those cases in which as a rule glycosuria of less than 1 per cent was exhibited in no more than one urinary specimen a day, as poor those in which the glycosuria was more marked, and as discontinued those cases in which because of excessive glycosuria or severe hypoglycemic reactions regular insulin was substituted for protamine zinc insulin. In nearly every instance the glycosuria was under as good or better control with protamine zinc insulin alone or in combination with regular insulin than with regular insulin alone; this experience coincides with the observations of McCullagh.³ Most of the failures with protamine zinc insulin were due to hypoglycemic reactions after exercise.

Coma or severe acidosis scarcely ever occurred while a patient was treated with protamine zinc insulin and seemed even less of a threat than with injections of regular insulin; this has been the experience at the New England Deaconess Hospital.¹² Ralli,¹ on the other hand, records the frequent incidence of coma in diabetic patients regulated with protamine zinc insulin.

RESULTS OF TREATMENT WITH PROTAMINE ZINC INSULIN

The summary of the results of the treatment of diabetes with protamine zinc insulin for this series of cases is given in table 1. It is satisfactory.

The failures that have been recorded in some clinics can be explained by two principal reasons: first, the impossibility of maintaining the blood sugar within physiologic limits for the twenty-four hour period, especially in severe cases, by means of protamine zinc

insulin alone; second, the unwillingness of many physicians to resort to regular insulin in conjunction with protamine zinc insulin when the combined use of a long and a short acting insulin is indicated.

As previously mentioned, we have not regarded hyperglycemia as a sign of failure of the effect of protamine zinc insulin, nor did we believe that all the benefits of fewer injections and freedom from hurrying for meals after the administration of insulin were completely lost when regular insulin was required with protamine zinc insulin. Our results with these provisos have been favorable but no more so than those of the clinicians who conceived the problems in the same way.

UPPER LIMITS OF DOSAGE WITH PROTAMINE ZINC INSULIN

Nearly all the more severely ill patients requiring a high dosage of insulin were receiving protamine zinc insulin combined with regular insulin and not protamine zinc insulin alone. This occurred because the first attempt was made to control the diabetes with protamine zinc insulin alone, and if this did not succeed regular insulin was added.

We believe that usually 40, at the most 50, units is the maximal satisfactory amount of protamine zinc insulin; when sugar in the urine persists, an increased dosage of protamine zinc insulin often fails to relieve the glycosuria occurring during the daytime and is very prone to cause severe hypoglycemic reactions in the early morning hours toward the close of the nocturnal fasting period. The hospitalized patients were in many

* The best control of the glycosuria and the least tendency to hypoglycemic episodes was as a rule achieved if the protamine zinc insulin was not pushed much beyond 40 units and was supplemented by injections of regular insulin when more insulin was required. The hospital patients with the large doses of protamine zinc insulin were more frequently afflicted with severe "insulin shocks" than the patients treated with smaller doses of protamine zinc insulin.

instances managed by higher doses of protamine zinc insulin than the ambulant patients, since the resident physician desired to effect control of the diabetes with only one injection of insulin. He succeeded in this, as shown by the large proportion of hospital patients receiving protamine zinc insulin only (table 2), but severe reactions were much more frequent.

The best control of the glycosuria and the least tendency to hypoglycemic episodes, as a rule, was

achieved if the protamine zinc insulin was not pushed much beyond 40 units and was supplemented by injections of regular insulin when more insulin was required.

In some instances large amounts of protamine zinc insulin have been used successfully. We have been informed of one case in which a daily injection of 160 units of protamine zinc insulin was given without untoward symptoms. However, in our experience,

TABLE 3.—Number of Injections a Day Required with Protamine Zinc Insulin in 114 Cases of Diabetes After Six Months or More on Protamine Zinc Insulin*

		No. of Cases	Per Cent
Total cases		114	
1 Injection	Protamine zinc Insulin only	76	66.7
	Protamine zinc and regular Insulin	8	7.0
2 Injections	Protamine zinc Insulin only	3	2.6
	Protamine zinc and regular Insulin	22	19.3
3 Injections	Protamine zinc Insulin only	0	0
	Protamine zinc and regular Insulin	5	4.4
4 Injections		0	0

* The comparatively small number of injections is obvious; it is especially noteworthy that 66.7 per cent of the cases were controlled by one injection of protamine zinc insulin and that in 76.3 per cent no meal except breakfast had to be taken on schedule to compensate for rapidly induced hypoglycemia which occurs after regular insulin.

especially in the ambulant cases, it has been much more difficult to stabilize the diabetes with a high dosage of protamine zinc insulin than when regular insulin was combined with a moderate dosage of protamine zinc insulin.

NUMBER AND TIME OF INJECTIONS OF PROTAMINE ZINC INSULIN

When injections of insulin become mandatory for the satisfactory control of diabetes it is universally agreed that the ideal procedure is to carry on with one dose of protamine zinc insulin administered before breakfast. In our series this was accomplished in seventy-six diabetic patients, that is in 66.7 per cent of the patients who had been treated with protamine zinc insulin for six months or longer (table 3). John⁹ reports 99 per cent success in reducing the dosage to once a day, a truly remarkable achievement.

The use of protamine zinc insulin every other day has been sufficient for the satisfactory control of some diabetic patients. Dr. Anna Spiegelman at the New York Post-Graduate Metabolism Clinic first called our attention to this possibility; McCullagh³ reports successful results with the injection of protamine zinc insulin at intervals of two days.

The question has been raised as to whether better results cannot be obtained by administering the protamine zinc insulin at some other time than before breakfast. It is obvious that an injection given on arising as part of the day's routine of dressing, bathing and the like is less disturbing to the patient than hypodermics at other hours when they necessitate retiring and partial disrobing. Since protamine zinc insulin acts for more than twenty-four hours, the time of injection would seem to be immaterial; however, it may be that the effect of the protamine zinc insulin is not constant and that this insulin may accelerate the dextrose metabolism more for the first eighteen hours than it will subsequently.

Some physicians believe that the administration of protamine zinc insulin in the evening produces better results than when given in the morning. Neuhoﬀ and

Rabinovitch¹³ reported one case which was controlled satisfactorily with an injection at 7 p. m. when the morning regulation failed. Observations carried out with blood sugar control over the twenty-four hour period in our experience gave no evidence of any advantage in altering the time of giving protamine zinc insulin. Neuhoﬀ and Rabinovitch¹³ found the lowest blood sugar values between 3 a. m. and 7 a. m. regardless of whether protamine zinc insulin was administered at 7 a. m., 7 p. m. or 10 p. m. We have concluded that in most diabetic cases it makes no difference at what time of day the protamine zinc insulin is employed and that using it before breakfast is the most acceptable for the patient, though there may be occasional instances in which injections in the evening are more effective. It would appear to be a matter for trial, when necessary, to determine what can be accomplished by varying the time of administration of protamine zinc insulin.

There were 76 patients in this series who received two injections of protamine zinc insulin a day (table 3). This was done early in the experience with protamine zinc insulin, when larger doses than 50 units were often administered because it was thought that half the daily dose could be advantageously omitted in the event of a hypoglycemic reaction. A few patients did well on such a regimen and consequently the method of treatment has not been changed. Neuhoﬀ and Rabinovitch¹³ found that splitting the dose of protamine zinc insulin in two did not control the blood sugar any better than one dose—in fact not so well in the difficult cases. It is also our final impression that the administration of multiple daily injections of protamine zinc insulin has no advantages over the single dose procedure.

FEWER INJECTIONS WITH PROTAMINE ZINC THAN WITH REGULAR INSULIN

A comparison of the number of daily injections of insulin in diabetes when treated by regular insulin alone and when regulated by protamine zinc insulin alone or in combination with regular insulin showed that distinctly fewer injections were required with protamine

TABLE 4.—Fewer Injections with Protamine Zinc Insulin Than with Regular Insulin*

* Seventy-six diabetic patients who had received two or more injections of regular insulin after six months or longer under treatment with protamine zinc insulin; the same number of injections were required in four cases, one less in thirty-two cases, two less in thirty-six cases and three less in four cases, making a daily saving of 116 injections for the seventy-six patients. (In this series when protamine zinc insulin and regular insulin were administered at the same sitting it is charted as one injection, although the needle was used twice.)

zinc than with regular insulin. (When protamine zinc and regular insulin were both administered in the morning this is credited as one injection, though the needle is used twice.) In only five of the 114 cases in this series were as many as three injections required, and in none of them were four injections necessary (table 3). In table 4 it is shown that in seventy-six cases of diabetes in which two or more injections of regular

13. Neuhoﬀ, Fritz, and Rabinovitch, Sam: Protamine Zinc Insulin: Clinical Observations and Comparative Analysis of Blood Sugar Curves Obtained with Use of Protamine Zinc Insulin and with Regular Insulin, Arch. Int. Med. 62: 447 (Sept.) 1938.

insulin were given and which had been followed by six months or longer of treatment with protamine zinc insulin, the same number of injections were required in four cases, one less in thirty-two cases, two less in thirty-six cases and three less in four cases, making a daily saving of 116 sessions with the hypodermic needle for seventy-six diabetic patients. The decrease in the number of injections is very real, according to this analysis, and the advantages for the patient are two-fold, not only because of the less frequent hypodermics but also for the reason that the meals after protamine zinc insulin need not be taken on a time schedule. Thus the diabetic patient's whole day becomes less hurried and tense.

COMPARATIVE REQUIREMENT OF PROTAMINE ZINC AND REGULAR INSULIN

The comparative requirement of protamine zinc and of regular insulin has been frequently reported; the usual statement is that fewer units of protamine zinc than of regular insulin are necessary for the control of

TABLE 5.—Average Increase or Decrease in Units of Insulin a Day with Protamine Zinc Insulin (or Protamine Zinc and Regular Insulin) Compared to Insulin Dosage in Preceding Period with Regular Insulin Only*

Average change.....	-19 (32 cases)	+ 4 (33 cases)	+ 3 (18 cases)

* There are fewer cases analyzed in this table than in the complete series because some patients had no initial period of regular insulin.

† The hospital patients received less protamine zinc than regular insulin, while the ambulant patients were controlled with slightly more protamine zinc than regular insulin. This difference in the requirement of protamine zinc and regular insulin between the two types of cases is probably more apparent than real and is attributed to a large dose method of administering regular insulin in the hospital patients and a more economical method of employing regular insulin in the ambulant patients.

any given case of diabetes. (The most important point at issue is whether protamine zinc insulin can regulate diabetes as effectively as regular insulin and with less exacting routine demands than regular insulin; the comparative dosage of protamine zinc and of regular insulin might well be considered a minor matter.) In our experience (table 5) there was a distinct difference between the hospitalized and the ambulant patients. Diabetic patients who were constantly under hospital supervision required less protamine zinc than regular insulin; while the office and dispensary patients called for a slightly greater amount of protamine zinc than regular insulin.

The reason for this difference in the two groups is not clear, though one explanation suggests itself. In the ambulant cases, during the period of management with regular insulin, the insulin was administered by what might be termed the economical method; that is, by relatively small but frequent injections. Hence the total daily dosage in units was relatively low, and when these diabetic patients were switched to protamine zinc insulin the comparative requirement was greater than would have obtained if regular insulin had been administered in larger amounts and fewer injections. On the other hand, in the hospital group an effort was made to regulate the diabetic patients with either two or three injections of regular insulin a day so that the total daily

amount of insulin was greater than if more frequent injections with a lower total number of units had been used.

The difference in dosage required between regular and protamine zinc insulin might therefore be regarded as one that depends very largely on the methods of administration that have been employed in the preceding period with regular insulin; some systems of regulation of the diabetes with regular insulin call for more insulin than others. We repeat that it seems to us a rather minor consideration whether more or less insulin is used and that freedom from restriction and avoidance of confining schedules should be used as the criteria for the acceptability of protamine zinc or regular insulin for any patient.

THE USE OF REGULAR INSULIN IN CONJUNCTION WITH PROTAMINE ZINC INSULIN

Some authors consider management of diabetes with protamine zinc insulin a failure when it has to be supplemented by injections of regular insulin. Many of our cases (thirty-five of 114, table 6) required regular insulin in addition to protamine zinc insulin for successful control. We believe this to be a distinct advance over the use of regular insulin only since the number of injections is materially reduced, hyperglycemia at night is prevented and there are a greater number of meals that need not be timed to follow closely on insulin injections.

The greater number of diabetic patients in the present series who received regular insulin in addition to protamine zinc insulin were in the high dosage brackets (table 7). This would be expected according to our system of dispensing protamine zinc insulin which limits the dose of protamine zinc insulin to 40, at the most 50, units and adds regular insulin when more insulin is required for the control of the diabetes. The detailed description of administering regular insulin in conjunction with protamine zinc insulin will be found in a subsequent section devoted to the regulation of dosage of protamine zinc insulin and protamine zinc combined with regular insulin.

DISADVANTAGES OF PROTAMINE ZINC INSULIN

The ideal effect of protamine zinc insulin is obtained when one dose of this insulin is given in the morning before breakfast and no further insulin is required during the day, and freedom from eating meals on time is achieved. This was accomplished in seventy-six, or 66.7 per cent, of our cases (table 3). Some observers, as previously mentioned, have achieved a greater degree of success, and some have not been as fortunate.

The lack of blood sugar control throughout the entire twenty-four hour period, the occurrence of slight or moderate glycosuria and the supplementary use of regular insulin have all been advanced as reasons for regarding protamine zinc insulin as a failure in diabetic management. We have not considered these conditions as indications for the discontinuance of protamine zinc insulin. We believe that the glycosuria, as a rule, is better controlled with protamine zinc insulin alone or in conjunction with regular insulin than with regular insulin alone. It must be remembered that there are many diabetic patients who do not respond well to either protamine zinc or to regular insulin. With such liberal criteria we have to record only four failures, or a 3.5 per cent failure in our series of 114 cases in which protamine zinc insulin was given for six months or longer (table 1).

The incidence of acidosis and coma was less frequent under a regimen of protamine zinc insulin than under regular insulin. With either insulin the development of a severe acidosis was not a common occurrence. The production of acidosis and coma may therefore, in our experience, be eliminated as an argument against the employment of protamine zinc insulin.

Hypoglycemia has been regarded as one of the serious drawbacks to the use of protamine zinc insulin.¹⁴ An editorial in THE JOURNAL called attention to the dangers of hypoglycemic reactions with a protamine zinc insulin

TABLE 6.—Number of Diabetic Patients Receiving Protamine Zinc Insulin Only and Those Cases Requiring Regular Insulin in Addition to Protamine Zinc Insulin After Six Months or More of Protamine Zinc Insulin Therapy

	No. of Cases	Per Cent
Total cases	114	
Cases treated with protamine zinc insulin only	79	69.3
Cases treated with protamine zinc and regular insulin	35	30.7

regimen which may be severe, even fatal, and appear without warning or follow exercise. Wilder some time ago quoted one of his patients who was using protamine insulin as saying that he no longer suffered from diabetes but now had insulin reactions. In the early days of using protamine zinc insulin reactions were plentiful; however, since we have learned to moderate the dose of both protamine zinc and regular insulin according to the scheme previously detailed, they have occurred less and less frequently and their intensity has been very much diminished.

The importance of exercise in causing hypoglycemia in patients under the influence of protamine zinc insulin has come to be realized. Physical exertion, sometimes even of moderate intensity, may result in devastating reactions. In one of our cases a walk of a quarter of a mile would result in unconsciousness from which the patient was rescued on three occasions by infusions of dextrose and then protamine zinc insulin therapy was abandoned. We have never encountered another case like this one, though the possibility of a similar susceptibility must always be remembered. In many diabetic patients, hard walking or golf results in hypoglycemic emergencies. We have for the last year advised diabetic patients to indulge in a considerable amount of carbohydrate-containing food, such as a sandwich and a glass of milk, before playing golf and the like so as to anticipate the combined effect of protamine zinc insulin and exercise on the blood sugar. This has been most successful. In a few cases of diabetes, when a combination of hard exercise and sunshine has been taken up during the summer, we have thought it advisable to discontinue the protamine zinc insulin and resort to regular insulin, because marked hypoglycemia and swimming did not seem compatible with safety; for the same reason an ardent aviatrix was asked to refrain from protamine zinc insulin and not to fly until five hours had elapsed after an injection of regular insulin.

In short, we believe that, by limiting the dosage of protamine zinc insulin to 40 units, as a rule, and supplementing this with carefully meted out regular insulin, when necessary, and by buffering the hypoglycemic tendency of exercise before the physical exertion is

indulged in, hypoglycemic reactions may be controlled and are no more frequent—if not less so—than they are with regular insulin.

REGULATION OF DOSAGE OF PROTAMINE ZINC INSULIN ALONE AND COMBINED WITH REGULAR INSULIN

Mild diabetes is usually controlled without difficulty by one injection of 20 units or less of protamine zinc insulin; the urine is continually free of sugar and the blood sugar maintains acceptable levels throughout the twenty-four hours. When the required dose ranges between 20 and 40 units of protamine zinc insulin, as a rule a late evening meal containing starch and protein becomes necessary to prevent the excessive lowering of the blood sugar during the night, which larger amounts of protamine zinc insulin bring about. In severe diabetes calling for more than from 40 to 50 units of protamine zinc insulin, the blood sugar is usually at a normal level throughout the night; but during the day, after eating, hyperglycemia and glycosuria often develop. A further increase of protamine zinc insulin might control the diurnal glycosuria but would be prone to overact during the fasting period at night and cause early morning hypoglycemic reactions, which are always disagreeable and may be serious. Forcing protamine zinc insulin under these circumstances will result in a miscarriage of the diabetes treatment and make this drug score a failure. In this dilemma the remedy lies in administering just enough protamine zinc insulin to control the blood sugar during the period of nocturnal fasting and to supplement it with short acting regular insulin to check the postprandial hyperglycemia and glycosuria.

The signs and symptoms, according to which the regulation of diabetes by protamine zinc insulin alone or combined with regular insulin is accomplished, are decidedly different from the data that guided treatment

TABLE 7.—Number of Patients Receiving Protamine Zinc Insulin Only and Those Receiving Regular Insulin as Well, at Various Dosage Levels

Dosage in Units	All Patients		Protamine Zinc Insulin Only		Protamine Zinc and Regular Insulin	
	Number	Per Cent	Number	Per Cent	Number	Per Cent

40 units or less	70	61.4	64	81.0	6	17.1
41 to 60 units	28	24.6	11	39.3	17	48.6
Over 60 units	16	14.0	4	5.1	12	34.3

when regular insulin was the sole insulin available. In some clinics a blood sugar curve covering the entire twenty-four hours is claimed to be necessary for evaluation of the effect of protamine zinc insulin. This is obviously impracticable in routine hospital, office or dispensary practice. The history and laboratory determinations at each visit should furnish information concerning two points:

1. What is the level of blood sugar between 3 a. m. and 6 a. m.?

2. Is there a postprandial glycosuria and after which meals does it occur?

There are numerous ways in which this information may be obtained. One objection, which it seems to us should not be lost sight of, is that it is very essential that a visit to the doctor should not necessitate an upheaval in the patient's daily routine from which it may be difficult to regain a balance; consequently, we

14. Danger of Protamine Insulins, editorial, J. A. M. A. 111:254 (July 16) 1938.

have not carried out blood sugar determinations in the fasting state nor have we asked for a twenty-four hour specimen of urine. The following procedures have been gradually evolved and have proved to be serviceable:

1. For the estimation of the early morning sugar level:

A. Careful inquiries are made regarding symptoms of hypoglycemia occurring between 2 and 3 a. m. and breakfast time; besides the usual complaints, it should be noted that headache, whether slight or severe, on awakening may be the only subjective warning. If there are any indications whatever of hypoglycemia, this condition should be presumed to have been present until further investigation has disproved its existence. The evidence of, or even a suspicion of, hypoglycemia calls for a reduction in the dose of protamine zinc insulin.

B. Examination is made of the specimen of urine voided on arising; if this contains more than 0.1 per cent of sugar, the blood sugar during the night has probably been greater than normal and the dose of protamine zinc insulin may be increased; if this sample of urine shows no sugar, the blood sugar may be relatively normal or too low and the protamine zinc insulin should not be raised but may be lowered if there are evidences of hypoglycemia, obtained from the patient's symptoms or blood sugar determinations.

C. Determination of the blood sugar at about 6 a. m. is very desirable but hardly ever possible; this gives a direct estimation of the fasting glycemia; hypoglycemia calls for a lowering of protamine zinc insulin and hyperglycemia for an increase. When the blood sugar is estimated from one-half to three hours after breakfast, as is generally done in private practice, the interpretation becomes somewhat intricate. A low blood sugar shows that the protamine zinc insulin is overactive after breakfast and that it should be diminished. A high blood sugar may either indicate an insufficient amount of protamine zinc insulin and an elevated fasting blood sugar or it may point to an extremely low early morning blood sugar from which the hypoglycemia has undergone a rebound to hyperglycemia through the mobilization of dextrose from liver glycogen. (One diabetic patient who through error had quadrupled her injection of protamine zinc insulin for several days showed a total absence of true dextrose in the blood at 6 a. m. on two successive days, and after her usual breakfast, without the addition of sugar or other food, the blood sugar at 10 a. m. rose to a level of 200 mg. per hundred cubic centimeters.) The differential diagnosis in regard to the significance of the hyperglycemia under these circumstances rests entirely on the patient's account of the early morning conditions. As a rule the degree of hypoglycemia is so marked that there is no doubt about its existence when the rebound phenomena occur, so that an elevated blood sugar after breakfast may be regarded as a sign of deficient protamine zinc insulin unless the patient's evidence indicates that there was a hypoglycemia early in the morning, in which case the hyperglycemia points to an excessive dose of protamine zinc insulin. This paradox cannot be ignored if the successful regulation of diabetes by protamine zinc insulin is to be accomplished.

2. For the determination of postprandial glycosuria:

A. Besides the urine on arising, previously mentioned, the specimen obtained two hours or more after the evening meal should be examined. If this contains no sugar, regular insulin is contraindicated. If it contains sugar, two methods of procedure suggest themselves. In case the morning urine also yields dextrose and the early blood sugar is elevated, the protamine zinc insulin may be increased; when it is not desirable to administer a larger amount of protamine zinc insulin, or if either the morning urine or blood sugar or both are normal, while the evening specimen contains sugar, then regular insulin may be employed in addition to the protamine zinc insulin. According to cold reasoning, the regular insulin should be given just before the evening meal. In many instances, however, it may be administered effectively before breakfast, dispatching all the insulin injections for the day at one sitting and making it obligatory to take only breakfast on schedule, which is not very difficult. This method of treatment was reported as successful in eight of our cases (table 3). When the urine does not become sugar free by these means, the

regular insulin should be given before supper only; if this is not completely effective, then regular insulin in conjunction with protamine zinc insulin is given both before breakfast and before supper. Treatment with regular insulin before all three meals is rarely required (five cases in our series, as shown in table 3).

A word of warning is necessary with regard to the size of the dose of regular insulin when it is given in combination with protamine zinc insulin. Regular insulin under these circumstances is much more potent than when it is the sole insulin. When it is given in addition to protamine zinc insulin, we have found it advisable to limit the initial dose of regular insulin to 4 or 6 units and raise by 2 unit increments to about 12 to 14 units once or twice a day, before breakfast, before dinner or both as the usual upper safe limit. There are occasional instances in which more insulin is well tolerated, such as one patient with hemochromatosis who is receiving approximately 50 units of protamine zinc insulin once a day, and 25 units of regular insulin twice a day. Occasional cases of this sort can be satisfactorily adjusted by persistent, judicious ventures in protamine zinc and regular insulin therapy.

889 Lexington Avenue.

THE USE OF HEPARIN IN BLOOD TRANSFUSIONS

S. W. SAPPINGTON, M.D.

PHILADELPHIA

Heparin as a natural anticoagulant has frequently been suggested for use in blood transfusions, but the difficulty in obtaining a pure and potent product free from toxic effects, as well as the high cost of production, has been a hindrance to its trial and use. Mason¹ in 1924 reported some experiments on thirty-three human subjects relative to the use of heparin in blood transfusions, but his product was too toxic for routine clinical purposes. Howell² in 1928 obtained a purified heparin which was tried out in transfusions on ten patients, apparently with good results, though subsequent reports of its use are wanting. In 1933 Schmitz and Fischer³ in Copenhagen and Charles and Scott⁴ in Toronto obtained heparin in a pure state. Jorpes⁵ showed that this pure heparin is a mucoitin polysulfuric ester. It is now being produced commercially and stable, potent preparations, apparently nontoxic, are now or soon will be available at a cost less prohibitive than formerly.

These new heparins have already been used as the anticoagulant in blood transfusions and the results have been reported by Skold,⁶ Tretow,⁷ Schürch⁸ and Clemens.⁹ These investigators employed the *in vitro*

method as in sodium citrate transfusions, adding the requisite amount of heparin to the drawn blood. Their results seem to have been satisfactory, though it is of some significance that three of them mention using large needles or cannulas, and two of them used paraffin in the receiving flasks. Hedenius¹⁰ followed a different procedure, an *in vivo* method, heparinizing the donor by giving intravenously a dose sufficient to render the entire volume of blood temporarily incoagulable, then at the appropriate time withdrawing the desired amount of blood and injecting it into the donor. This method has been tried in more than 150 blood transfusions and has been so successful that Hedenius states that in the Sabbatsberg and Serafiner hospitals in Stockholm it is used as a routine, having replaced the citrate and whole blood methods. Knoll and Schürch¹¹ also have reported on the successful use of the Hedenius method.

The investigations herewith reported concern the use of heparin by *in vitro* and *in vivo* methods in a series of blood transfusions. The heparin we employed is the same used by Hedenius and is a stable, sterile 5 per cent solution of the drug.¹² It contains 500 units per milligram, the unit of heparin being defined as that amount of substance which will prevent the clotting of 1 cc. of cat's blood for twenty-four hours when kept in the cold. The unit of heparin has a different meaning with different preparations but the high potency of this product is evident. The amount recommended to add to 500 cc. of drawn blood is 20 mg. (0.4 cc. of the 5 per cent solution); this maintains the fluidity of the blood for many hours. The dose for heparinizing the donor by intravenous injection (Hedenius method) is 1 mg. per kilogram of body weight; this is usually from 70 to 75 mg., or approximately 1.5 cc. of the 5 per cent solution. After such a dose, the blood shows within a few minutes marked lengthening of the coagulation time, and this persists for from thirty to sixty minutes or more, giving ample time for the withdrawal of this relatively incoagulable blood and its injection into the patient. Seven minutes after the injection of the donor, the withdrawal of his blood is begun and usually completed three or four minutes later. This heparinized blood will have no effect on the patient as far as altering the coagulation time. If, however, heparin is added to blood *in vitro* in certain amounts and given to the patient, the coagulation time may be altered. To effect this a certain threshold dose must be exceeded, which is 0.25 mg. per kilogram of body weight. Apparently only the coagulability of the blood is affected, as up to 4 mg. per kilogram has been given to man without toxic effects. And in rabbits it has proved nontoxic up to 100 mg. or more per kilogram when injected intravenously.

TECHNIC

The sodium citrate method is easily the dominant method of blood transfusion, and a new procedure must face comparison with it. About 1,200 citrate transfusions are done at the Hahnemann Hospital in a year, and the method is so standardized that there are few or no technical difficulties. For the purpose of comparison, our heparin transfusions were done as far as possible with the same technic. This, in brief, consists in collecting the blood in two 250 cc. cylinders, citrating

it at the same time by adding the appropriate amount (0.3 per cent) of 10 per cent sodium citrate as each 50 cc. of blood is collected, after which the blood is given the patient by the gravity method, an 18 gage needle, long rubber tubing and a 250 cc. buret being used. It takes three or four minutes to collect 500 cc. of blood and from ten to twelve minutes to give it. The heparin transfusions were done in the same way, the same apparatus and the same procedure being used in the case of blood heparinized after withdrawal, and such modifications being instituted as were essential when the donor was heparinized before the blood was withdrawn. Forty heparin transfusions were done, seventeen by the *in vitro* and twenty-three by the *in vivo* method. All were purposely of 500 cc. We used this larger amount because almost any method of transfusion may be successful with small amounts such as from 250 to 300 cc. but not infrequently works poorly with amounts of 500 or 600 cc. of blood.

TRANSFUSIONS WITH BLOOD HEPARINIZED AFTER WITHDRAWAL

The blood for these seventeen transfusions was collected as already indicated for the citrate method and heparin, diluted in saline solution, added fractionally to each 50 cc. of blood. The total amount of heparin added to each 500 cc. varied from 20 mg. (0.4 cc.) to 150 mg. (3 cc.) according to the nature of the experiment. A small portion of each specimen of heparinized blood, 5 or 10 cc., was poured into a test tube and retained to note the time of clotting. In no instance was there any clotting before three days, after which the specimen was usually discarded. In one case, in which only 25 mg. of heparin was added to the 500 cc., the blood was fluid at the end of nine days.

When to 500 cc. of donor's blood was added from 20 to 25 mg. of heparin, amounts which cause no change in the patient's coagulation time, and the transfusion given with an 18 gage needle, it was found that, though the first 250 to 300 cc. was transfused rapidly and without delay, the flow then began to slow and usually stopped when from 350 to 400 cc. of blood had been given. It was ascertained that this was due to clotting within the needle but not within the rubber tubing or buret. When a 17 gage needle was used the transfusions proceeded without interruption, though the flow slowed, often considerably, with the last 150 cc. When a 16 gage needle was used, the whole operation was accomplished with ease and rapidity. In two instances, bloods heparinized with 20 and 25 mg. were banked and transfused without difficulty after twenty-four and forty-eight hours respectively, with a 16 gage needle.

When the flow of blood stopped, say at from 350 to 400 cc., because of blockage within the 18 gage needle, the transfusion was completed successfully by making another venipuncture with a fresh needle. It was thought, however, that the entire transfusion might be accomplished with one puncture and a small needle if more heparin was added, and this was tried. Amounts of 40, 50, 75, 100 and even 150 mg. were added to the blood instead of the usual 20 or 25 mg. The complete transfusion of 500 cc. was then successful with an 18 gage needle, the success as measured by the ease and rapidity of the transfer being roughly proportionate to the amount of heparin added. In this connection, we in one instance added 75 mg. of heparin to 500 cc. of blood and banked it forty-eight hours, at the end of which time it was transfused without trouble with a small needle.

12. This heparin is prepared after the method of Charles and Scott under the direction of Jorpes and is marketed by Firma Vitrum, Stockholm. Tretow and Clemens used a German preparation, Vetren, put out by Promonta of Hamburg; Schuerch, a Swiss product of Hoffmann-La Roche Company of Basle.

The addition of such amounts of heparin exceeds the threshold dose of 0.25 mg. per kilogram of body weight, and a lengthening of the coagulation time was anticipated. In all instances the bloods showed a normal coagulation time before transfusion. When 50 mg. of heparin was added to the blood transfused, the patient's blood showed a clotting time of seventy-three

minutes immediately after completion of the transfusion, or from fifty to sixty minutes a half hour later and a gradual drop to normal in an hour or two. With an addition of 100 mg. the patient's coagulation time immediately and thirty minutes after the transfusion was about two hours. With 150 mg. of heparin, the patient's blood removed fifteen and sixty minutes after the transfusion remained unclotted for sixteen hours. This lengthening of the clotting time might be an advantage or disadvantage to the patient: an advantage if the danger of thrombosis was present or expected; a disadvantage if the patient is in shock¹³ or there is a hemorrhagic tendency. At any rate our patients suffered no ill effects whatever from the larger amounts.

TRANSFUSIONS WITH HEPARINIZED DONORS

With some exceptions the donor's dose of heparin was approximately 1 mg. per kilogram of body weight, or about 1.5 cc. of the 5 per cent solution injected intravenously. In table 1 are seen the results of the examination of the blood of donors before and after the injection of heparin and withdrawal of 500 cc. of blood. It will be noted that the hemoglobin and the red and white cell counts are almost the same or exhibit an insignificant reduction. Likewise the platelet count shows only a slight and unimportant drop. These counts are also a comment on the immediate effect of losing 500 cc. of blood. The bleeding time, while not tested specifically, was noted when the foregoing counts were made, and it was observed that while there was no increased bleeding with low doses there was a slight increase of bleeding time with large doses of heparin.

The effect on the donor's coagulation time is seen in table 2. All coagulation tests were done by the Lee and White method with blood taken from the vein of the uninjected arm. The end point by this method is later than by various other methods. It will be noted that the lengthening of the clotting time after heparin is prompt and striking but that there is considerable varia-

tion in the coagulation time in different donors even with the same dose of heparin. Part of these variations we cannot explain. Part is probably due to the fact that at the beginning of the work we injected the small amount of heparin rapidly and undiluted, whereas later we injected it more slowly and finally we injected it very slowly diluted with 5 or 10 cc. of saline solution, thus insuring better dispersion throughout the entire blood volume. In the later cases in which this method was in vogue and two minutes was taken for the injection, it will be seen that, while the coagulation was normal before injection, it changed in one minute so that the clotting time was increased to an hour or more and remained lengthened from thirty to sixty minutes. It was difficult to keep donors in the laboratory after an hour, so in many instances there are no tests after this time. When larger doses of heparin were given, the prolongation of blood fluidity was still more marked. In donor 18, who received 4 mg. per kilogram, or 5 cc. of the heparin solution, the one, thirty and sixty minute bloods remained uncoagulated two days and the two hour blood one day. This donor returned to the laboratory in two days, when his blood clotted in sixteen minutes and he reported no ill effects. Donor 23 received 2 mg. per kilogram and his clotting was watched with special care. The blood that clotted in fifteen minutes before the injection of heparin did not clot for nine hours in the specimen taken one minute after the injection of heparin, as well as in ten, thirty and sixty minute specimens. The blood of the two and one-half hour specimen clotted in three hours and that taken in three and one-half hours clotted in ten minutes. In a case not included in the list but observed especially for the clotting phenomena, the donor received only 1 mg. per kilogram. His blood one minute after the injection of heparin coagulated in 170 minutes, after sixty minutes in 120 minutes and after

120 minutes in sixty minutes. None of these donors had the slightest ill effect from small or large doses of the drug, which is a tribute to its nontoxicity.

The withdrawal of the donor's heparinized blood was begun seven or eight minutes after injection, and the patients were given the blood at once. The patients were tested for coagulation time before and sixty minutes after the transfusion and showed no change except when excessive doses of heparin had been given the donor, as in cases 17, 18 and 23. The results experi-

13. Murray, G. D. W., and Best, C. H.: The Use of Heparin in Thrombosis, *Ann. Surg.* 108: 163-173 (Aug.) 1938.

enced in giving blood heparinized in vitro were duplicated when we transfused blood heparinized in vivo. When 18 gage needles were used, the blood flowed freely for the first 350 cc. and then slowed to stopping, requiring repuncturing with another 18 gage needle, after which the transfusion was completed without difficulty. Since blood clots slower in larger containers than in narrow cylinders, we attempted to avoid this by collecting the blood in a 500 cc. flask unparaffined in one instance and paraffined in another. Both experiments were unsuccessful, the blood clotting within the needle when from 420 to 450 cc. had been given. It seems evident that the difficulty is in the passage of the blood through the narrow channel of the small needle, the friction probably aiding thrombotic factors. We therefore relied mostly on a 16 gage needle, with which the transfusion was uniformly successful. Tretow, Schuerch and Clemens, without giving the size, mention using large needles or cannulas and probably experienced the same trouble. One objection to the large needle is the speed of the transfusion, the time in our cases being only from three to five minutes. The patients, however, suffered no circulatory or respiratory embarrassment even when the transfusion was given as rapidly as three minutes. We do not think it is desirable to give rapid intravenous injections of blood or any fluid, but our experience here shows that 500 cc. of blood may be transfused in from three to five minutes without objectionable effects.

SEQUELAE

Judging from the results of these forty transfusions, the heparin used was free from toxic effects. None of the twenty-three donors injected intravenously with the drug suffered the slightest ill effects immediately or later. Nor did the recipient patients show any early or late effects which could be attributed to the heparin. Two of the forty patients had a chill and a rise in temperature within an hour after the transfusion, but this incidence is no higher than with transfusions of blood treated with sodium citrate. In another case urticaria developed right after the transfusion, but a similar attack of hives had occurred after a transfusion with citrated blood a few days previously.

SUMMARY

A stable, potent, pure heparin was used as the anti-coagulant in forty blood transfusions and appeared to be without toxic or other undesirable effects on donor or patient. It was used in two ways: first, in vitro to heparinize the drawn blood from the donor; second, in vivo to heparinize the donor by intravenous injection. The first corresponds to transfusion of citrated blood and differs from it only in the anticoagulant. The second method is simpler in that the heparinized blood is withdrawn from the donor and introduced into the patient without any treatment outside the body. Seventeen patients were given transfusions by the first method and twenty-three by the second, all with 500 cc., since a larger amount of blood was thought a better test of the procedure. These were all done by a gravity method paralleling the citrate technic in order that comparison of the two anticoagulants could better be made.

All forty transfusions were successful in that the entire amount of blood was transfused and the donors and patients suffered no ill effects. But it was found that for a successful, uninterrupted transfusion a larger needle was necessary for introduction into the patient than in the citrate method, in our experience a 16 gage needle as against the 18 gage commonly used in citrate

transfusion. If a 500 cc. transfusion is desirable, this has a disadvantage in that the patient's veins may be difficult to enter with such a large needle. If a small transfusion is sufficient, up to 350 or even 400 cc. may be given without difficulty with an 18 gage needle. Or the operation of giving 500 cc. can be accomplished by giving as much blood as will flow through the small needle and then completing the transfusion by making another venipuncture with a fresh 18 gage needle. We did this a number of times and the two punctures caused little or no discomfort to the patient. This hindrance to the heparin transfusion is caused by clotting within the smaller needle, even though the same heparinized blood may be kept days without clotting. In one instance blood was banked twenty-four hours and in three instances forty-eight hours and then transfused successfully. Reactions are negligible, as they are now in transfusions with citrated blood. Whether the heparin method can displace the well established citrate method remains to be seen. It would seem to offer two advantages. The heparinization of the donor makes the procedure more simple and almost a one man job. The therapeutic value of heparin may be of advantage in postoperative transfusions.

Rock Creek Road.

CRYPTORCHIDISM

WILLIAM W. JOHNSON, M.D.

NEW YORK

For the past two or three years the medical literature has been filled with numerous reports as to the effect of endocrine therapy on cryptorchidism. In the main the accounts of successes have been glowing indeed. The published data have been pounced on by all the drug firms which distribute endocrine products, and the desk of every physician in the land has been deluged with reprints and advertisements. The idea of endocrine therapy for undescended testis has been "sold" to the medical profession.

Every one has heard all about the results of this method of treatment and is familiar with the happy outcome. Therefore I shall not take time to quote the many statistics which have been presented. In general it will suffice to say that in the compiling of a group of published results 179 cases were found of successful treatment and seventy-four of unsuccessful treatment, or 62 per cent of good results and 38 per cent of failures.

Previous to this onslaught the surgeon treated cryptorchidism by surgical measures. Not long ago the various authorities advised operation at all ages from 3 to 11, the consensus narrowing the limits from 9 and 11 years. Yet all agreed that the testis should be placed in the scrotum before the onset of puberty.

With the surgical teaching as a basis and the endocrine ballyhoo thundering in my ears, it occurred to me that I was in a unique position to obtain a standard by which the value of the two methods could be compared and a definite base line drawn. The results of my study have led to an interesting group of figures, which may be of value in comparing future therapeutic results.

STATISTICAL STUDY

For the past seven years I have had charge of the physical examinations of the boys who have joined the Boys Club of New York at the Jefferson Park Build-

ing. These boys are from the group of underprivileged children who inhabit New York's upper east side. Financial aid for the project has been difficult to obtain, so that medical service by the organization has been limited to physical examinations. Boys with serious defects have been referred to the large city clinics for

* Operated on by orchidopexy only; all others had hernia also.

care. It has thus come about that, while many defects have been noted, only the serious ones have been treated.

Boys of all ages from 7 to 17 have been examined year after year. Consequently there has been formed a group of boys in whom undescended testes were found, who were given no therapy and for whom follow-up examinations were done.

The study comprises a group of 544 cases of undescended testes observed from 1931 to 1937 inclusive. These cases were found during the examination of 31,609 boys, an incidence of 1.72 per cent, approximately seventeen cases per thousand boys.

After the World War, United States Army statistics showed that there were approximately two cases of undescended testes per thousand recruits examined. If there is no such thing as spontaneous descent, as has been declared by some writers, what happened to the fifteen cases per thousand? Surely this discrepancy in figures is not the result of surgical procedures.

In the 544 cases of undescended testes, careful examination revealed bilateral undescended testes plus Fröhlich's syndrome in seventeen cases and unilateral undescended testis plus Fröhlich's syndrome in eleven cases, or a total of twenty-eight cases of associated Fröhlich's syndrome. Undescended testis was associated with hernia in thirteen cases, malnutrition in five, hypospadias in two and congenital heart disease in two.

Fröhlich's syndrome has been seen often during these examinations, but there are comparatively few cases in which undescended testes are associated.

The relation of hernia to cryptorchidism in this series is interesting. One hears today over and over the ancient dogma "the undescended testis is always accompanied by a hernia." It may be true that hernial sacs are present with this condition and many of the patients may have a definite hernia at some future date, but surely this is no valid excuse for recommending surgical intervention in every case.

RESULTS OF TREATMENT

In spite of the poverty at the Boys Club, some of the boys have received treatment at various hospital clinics throughout the city. In all, nineteen have undergone therapy.

In five cases endocrine products were injected. In all the testes failed to descend when treatment was declared adequate and injections were stopped. These figures are of no appreciable value except in that the boys were all between the ages of 7 and 9 years, when it is admitted that endocrine therapy is of doubtful value.

In four instances orchidopexy was performed for the purpose of placing the testis in the scrotum. In ten it was performed in conjunction with the repair of definite hernia. A total, then, of fourteen operations to replace the testes have been done by various surgeons.

In evaluating the results of operation for this condition, all authors have designated the outcome as good, fair or poor. I do not believe that this is an honest method of reporting results.

In each operation for undescended testis there are three results to be obtained: 1. The testis should lie

in its normal low-scrotal position. 2. It should be firm in consistency. 3. It should be normal in size. Each of these results may be good, fair or poor. Thus, in reporting the results in this series of fourteen cases I kept in mind that there are actually forty-two optimum conditions to be obtained, and the results according to this system are tabulated in table 2.

In an effort to obtain forty-two good results, only twelve were obtained, a poor showing. Just how to

evaluate the twenty-five fair results is a matter of opinion. The small, soft testis high in the scrotum probably retains its endocrine function but not its spermatogenic one. In my opinion therefore, when the testis is of this type after operation the results should be classed as poor, since even without operation and with continued inguinal position the testis may function as well. If for the sake of argument I choose so to classify the fair results, the results become good twelve and poor thirty—abominable.

OUTCOME WITHOUT TREATMENT

In thirteen of the 246 cases of bilateral undescended testes, the two testes did not behave in the same way. The testes descended spontaneously but one preceded its fellow into the scrotum. The interval in ten instances was one year, in two instances two years and in one instance three years.

When these thirteen and the fourteen cases in which operation was performed are eliminated, there remain 517 cases to be considered. Many of these have been observed year after year and therefore are of great interest. Because the boys who visit the club come from the class of people who are frequently on the move, many of the cases have been lost. The average turnover year by year in the entire club is approximately 29 per cent. If this average holds true among the boys in this study, one would expect to lose about 157 cases. At the end of the survey there were 217 cases of undescended testes remaining or lost. If the number of boys with the condition found in the last year of examining (1937) who have not been reexamined to determine the fate of the testes (sixty-three) is added to those one might expect to lose because of the average turnover of boys (157), the expected number of cases of testes still undescended would be 220; actually it is 217.

Tables 3 and 4 have been prepared to show the age at which spontaneous descent occurred or the age at which nondescent was found at the last examination.

Table 3 shows that spontaneous descent resulting in a normal testis as to size, consistency and position occurred in 300 instances: 162 cases of bilateral and 138 cases of unilateral undescended testes. May this forever dispel the saying "spontaneous descent is so rare that operation should never be postponed on this account."

It is to be noted that between the ages of 11 and 13 the testes descended spontaneously in 174 cases without therapy of any kind. Between these ages the youth becomes the adolescent; the voice changes, the pubic hair develops and all the secondary sex characteristics manifest themselves because of a glandular readjustment. Now it is found that also during this period descent occurs in the undescended testis. In reviewing the statistics of advocates of the glandular treatment it immediately becomes apparent that it is at approximately the same age that their therapy is effective. Rarely can an undescended testis be enticed into the scrotum by glandular therapy before this age unless the therapy is pushed to the extent of bringing on premature adolescence and the secondary sex characteristics. So one may conclude that glandular therapy before the age of puberty is useless (no results) or harmful (bringing on premature adolescence) and at the age of puberty is unnecessary. At best it can be considered only an adjunct of doubtful value.

So far as surgical intervention is concerned, it is time to reconstruct all the old ideas. If operations

"before 11" had been carried out in this group of cases, 232 useless and detrimental procedures would have been performed. These figures show that operation before the sixteenth year would have been a definite mistake in most instances. Tables 3 and 4 show that after the fifteenth year there were still sixteen cases of nondescent, and in seven of these descent occurred spontaneously. I would suggest a new tenet "Do not operate for undescended testis before the sixteenth year unless operation is indicated by some associated condition."

SUMMARY

In 313 of 544 cases of cryptorchidism spontaneous descent occurred; operation was performed in fourteen instances. No follow-up examinations were made after discovery of the condition in sixty-three instances, and 154 patients were lost. Undescended testis as a manifestation of Fröhlich's syndrome is not of frequent occurrence and as a companion to other congenital defects is rare. In the fourteen cases of orchidopexy here discussed the results, evaluated according to a new system, were extremely discouraging. Judged in the light of the outcome without therapy, endocrine therapy should be used only as an adjunct to oncoming puberty and is in reality not a necessity. Orchidopexy should not be attempted before the sixteenth year unless indicated by some associated condition.

CORONARY ATHEROSCLEROSIS IN DIABETES MELLITUS

A POSTMORTEM STUDY

HOWARD F. ROOT, M.D.

EDWARD F. BLAND, M.D.

WILLIAM H. GORDON, M.D.

AND

PAUL D. WHITE, M.D.

BOSTON

Coronary atherosclerosis manifested clinically by angina pectoris and coronary thrombosis has become an increasingly important cause of disability and death in the United States, especially among the business and professional leaders of the community. Its unusual frequency in patients with diabetes mellitus makes a study of the possible factors responsible for this increase important not only in relation to diabetes but also to coronary disease in the general population. More than one half of the 500,000 living diabetic patients in the United States are destined to die of some form of occlusive vascular disease, of which coronary sclerosis is the most important. Among nondiabetic patients, coronary artery disease is apparently largely responsible for the relatively recent and striking increase in deaths from heart disease in middle and late life. Between 1930 and 1934 the mortality from recognized coronary disease increased from 4.7 to 18.8 per hundred thousand in the experience of the Metropolitan Life Insurance Company, according to Dublin.¹

Dr. Gordon is in the United States Public Health Service.
From the Massachusetts General Hospital and the George F. Baker Clinic, New England Deaconess Hospital.
1. Dublin, L. L., in Levy, R. L.: Diseases of Coronary Arteries and Cardiac Pain, New York, Macmillan Company, 1936.

THE PRESENT STUDY

It is only within comparatively recent times that special interest in the coronary arteries has become sufficiently acute for descriptions of these vessels and the associated lesions to be carefully and uniformly made at autopsy. This information is the most impor-

tant basis for statements as to the frequency of coronary artery disease and has accumulated sufficiently for comparative studies to be made in large series of cases only in relatively recent years. For our present purpose the records of autopsies on 349 patients with diabetes mellitus performed since 1921, consisting of fifty-seven from the Massachusetts General Hospital and 292 from the New England Deaconess Hospital, have been utilized for comparison with 3,400 autopsies on nondiabetic patients performed at the Massachusetts General Hospital since 1925. It is believed that this series of 3,400 autopsies on nondiabetic patients at the Massachusetts General Hospital is a representative cross section of the general population in this vicinity, since it includes many postmortem examinations on young patients as well as on those in middle and later life from a hospital which embraces not only adult services, both medical and surgical, but pediatric and orthopedic services as well, and represents all economic levels of the community (the poor, persons of moderate means and the well-to-do). Our diabetic series, unlike those from the larger European clinics reported in the nineteenth century, is not made up solely of patients dying soon after the onset of diabetes but includes a considerable number of patients followed over a long period of time. Furthermore, this diabetic series represents all economic levels of the community, as does our nondiabetic series.

The possibility of subdividing the atherosclerotic lesions in the coronary arteries in great detail was considered, but a simple classification of the lesions was finally adopted. The cases were arranged by sex and age at death into four general groups according to the condition of their coronary arteries post mortem: first, cases without macroscopic evidence of atherosclerosis; second, cases showing atherosclerosis as indicated by fatty plaques or calcification but without significant narrowing of the lumen; third, atherosclerotic changes

with definite narrowing of the lumen of one or both coronary arteries or their major branches; fourth, cases showing an actual occlusion of a coronary artery, either recent or healed and with or without myocardial infarction. Tables 1 and 2 include the pertinent data from the autopsies on 349 diabetic patients and 3,400 non-diabetic patients.

SEX

A striking difference between the diabetic and non-diabetic groups appears in the total distribution of cases by sex. In the diabetic series only 45 per cent were males and 55 per cent females, whereas in the non-diabetic series 63.3 per cent were males and 36.7 per cent were females.²

Under the subject of sex should be mentioned the possible influence of hypertension. We have not attempted as yet to make a complete analysis of the influence of hypertension in the two comparable series. However, it may be noted that in 292 of the autopsies on diabetic patients hypertension was present in only forty-nine male in contrast with ninety-five female patients.

AGE

Coronary Occlusion.—Under the age of 40 there were two of thirty-three diabetic patients (6 per cent) with coronary occlusion, while there were seven of 1,090 nondiabetic patients (0.6 per cent) with coronary occlusion. Between the ages of 40 and 60 there were thirty-one of 132 diabetic patients (23 per cent) with

* Fifty-seven diabetic cases included in the previously published series from the Massachusetts General Hospital (to be published in the American Heart Journal) have been replaced by the next consecutive fifty-seven nondiabetic cases from the autopsy protocols.

coronary occlusion and eighty of 1,273 nondiabetic patients (6 per cent) with coronary occlusion. Between the ages of 60 and 80 there were seventy-six of 175

2. It is a curious fact that within recent years mortality rates for diabetes have shown a preponderance among females. Although in general a large number of diabetic patients coming for treatment seems to show an almost even division between the sexes, actually the death rates indicate in recent years a steady increase in female mortality. It has been thought that this preponderance in female mortality is to be largely accounted for by the fact that only within recent years have females received medical attention comparable to that received by males and that therefore the preponderance of diabetic female mortality is due to the factor of improved diagnosis in women at present and of more careful treatment given to men in the past.

diabetic patients (43 per cent) with coronary occlusion and 102 of 977 nondiabetic patients (10 per cent) with coronary occlusion. Over the age of 80 there were three of nine diabetic patients (33 per cent) with coronary occlusion and seven of sixty nondiabetic patients (11 per cent) with coronary occlusion. Thus, for all ages, coronary occlusion occurred in 112 of 349 diabetic patients (32 per cent) as compared with 196 of 3,400 nondiabetic patients (6 per cent).

Coronary Narrowing Without Occlusion.—Under the age of 40, coronary narrowing without occlusion occurred in one of thirty-three diabetic patients (3 per cent) and in eight of 1,090 nondiabetic patients (0.7 per cent). Between 40 and 60 years of age there were twenty-three such cases among 132 diabetic patients (17 per cent) and 159 such among 1,273 nondiabetic patients (12 per cent). Between 60 and 80 years of age there were forty such cases among 175 diabetic patients (22 per cent) and 295 among 977 nondiabetic patients (30 per cent). Over the age of 80, coronary narrowing without occlusion occurred in four of nine diabetic patients (44 per cent) and in thirty of sixty nondiabetic patients (50 per cent). For all ages there was thus significant coronary narrowing in sixty-six of 349 diabetic patients (19 per cent) compared to 492 of 3,400 nondiabetic patients (14 per cent).

No Significant Coronary Atherosclerosis (no narrowing of the lumen).—Under the age of 40, no significant coronary sclerosis was noted in thirty of thirty-three

(table 4). In nondiabetic patients, on the other hand, coronary occlusion is five times as frequent in males as in females between the ages of 51 and 60, but from 61 to 80 years of age the two sexes become almost the same. The excessive frequency of coronary occlusion in diabetic patients as against nondiabetic patients, however, continues late in life.

TABLE 4.—Coronary Occlusion in Diabetic and Nondiabetic Patients in Percentage of Cases in Age Groups

Age Groups	Males				Females			
	Diabetic		Nondiabetic		Diabetic		Nondiabetic	
	Cases with Occlusion	Per Cent of Total	Cases with Occlusion	Per Cent of Total	Cases with Occlusion	Per Cent of Total	Cases with Occlusion	Per Cent of Total
41-50.....	2	15	23	7	3	11	2	1
51-60.....	13	33	47	10	13	25	8	3
61-70.....	28	48	52	11	26	40	17	7
71-80.....	9	41	24	11	13	43	9	10

It is not possible to attribute so high an incidence of coronary thrombosis in both male and female diabetic patients merely to the prolongation of diabetic treatment and the aging of the diabetic group. It is not possible to assume that there has been any selection in the cases. At the New England Deaconess Hospital, where the majority of the diabetic patients were studied, the distribution of patients among ward patients in contrast to private room patients is about the same as at

TABLE 3.—The Degree of Atherosclerosis in Diabetic and Nondiabetic Patients According to Age

diabetic patients (91 per cent) and in 1,075 of 1,090 nondiabetic patients (98 per cent). Between 40 and 60 years of age there were seventy-eight such cases among 132 diabetic patients (59 per cent) and 1,034 such among 1,273 nondiabetic patients (81 per cent). Between 60 and 80 years of age there were fifty-nine such cases among 175 diabetic patients (35 per cent) and 580 among 977 nondiabetic patients (59 per cent). Over the age of 80 no significant coronary sclerosis was found in two of nine diabetic patients (22 per cent) and in twenty-three of sixty nondiabetic patients (38 per cent). Thus for all ages there was no significant coronary sclerosis in 170 out of 349 diabetic patients (49 per cent) compared to 2,712 out of 3,400 nondiabetic patients (82 per cent).

The crucial point is the duration and severity of the diabetes. Among 140 diabetic patients without significant atherosclerosis, fifty-seven had had diabetes less than three years and seventy-six for less than five years. Unusual mildness characterized thirty-two cases of diabetes of more than ten years' duration.

It is thus evident that the difference between the diabetic and the nondiabetic patients is greatest in those showing actual occlusion of a coronary artery. In the diabetic series coronary occlusion from the age of 51 to 80 years is almost the same in males and in females

the Massachusetts General Hospital, where cases both from private wards and from the public wards are included.

COMMENT

In order to explain the excessive development of coronary disease in the diabetic patients of this series, any or all of the contributing factors usually considered in coronary atherosclerosis are illustrated, but no single one provides an adequate answer. Aging of the arteries must certainly be accepted as of fundamental importance, even though it must be granted that arteriosclerosis of the coronary arteries may occur—and rarely does occur—even at very young ages. An outstanding feature in the diabetic group has been the disturbance in the cholesterol metabolism as evidenced by visible lipemia or by elevation of the plasma cholesterol at certain stages of the diabetes. The more advanced degrees of coronary atherosclerosis occurred in the patients whose diabetes was of long duration, whereas absence of significant atherosclerosis was noted in cases of short duration or of unusual mildness.

Among seventeen diabetic patients who had multiple infarction of the heart, ten were males and seven females. The average duration of diabetes in these cases was 10.9 years for the males and 9.2 for the females. In one striking instance the patient, aged 28

at onset of diabetes, had lipemia when he was 33. At death ten years later eight distinct healed areas of infarction were found. Death occurred from an acute coronary occlusion. Similarly, in another instance, lipemia retinalis occurred at the age of 21.

SUMMARY

1. A comparison of atherosclerotic lesions in the coronary arteries of 349 diabetic patients and 3,400 nondiabetic patients at autopsy has been made according to sex and decade of age.

2. Coronary occlusion in this series was much more frequent in diabetic than in nondiabetic persons, the difference, for example, in the age group from 40 to 60 being 23 per cent (thirty-one of 132 cases) for the diabetic as compared to 6 per cent (eighty of 1,273 cases) for the nondiabetic patients.

3. Coronary narrowing without occlusion was also found more commonly in the diabetic than in the nondiabetic patients under the age of 60; for example, 17 per cent compared to 12 per cent in the age group of 40 to 60.

4. Significant atherosclerosis with occlusion or narrowing was absent in 49 per cent of the diabetic patients and 82 per cent of the nondiabetic patients.

5. Occlusion of a coronary artery occurs in diabetic women almost as frequently as in diabetic men, whereas in nondiabetic patients it is far less frequent in women than in men up to the age of 60.

THE SIGNIFICANCE OF VULVOVAGINITIS IN PREGNANCY

EDWARD G. WATERS, M.D.

JERSEY CITY, N. J.

AND

EAKLE W. CARTWRIGHT, M.D.

SAN DIEGO, CALIF.

The occurrence of vulvovaginitis during pregnancy is of more than casual interest because of certain possible or presumed effects on the maternal or fetal organism. Only recently has the monilia been frequently noted, and the clinical importance seemingly is still uncertain. In our experience, several years of clinical observation of a specific type of vulvovaginitis caused by the monilia group produced confusing opinions and few satisfactory or reliable conclusions.

To test the validity of existing concepts, a series of 500 unselected pregnant women were studied (1) to find the incidence of monilial vulvovaginitis in pregnancy, (2) to obtain the incidence of subjective signs and symptoms in pregnant patients with moniliasis, (3) to determine the association, if any, of puerperal morbidity in a group with moniliasis as compared with a control group, (4) to note the association and significance of possible pathogens and other organisms with the monilia, (5) to record the frequency of neonatal thrush in the newborn of mothers with moniliasis as compared with the newborn of mothers without moniliasis and (6) to determine the hydrogen ion concentration of the vaginal secretions in pregnancy with and without moniliasis.

METHOD FOR COLLECTING SPECIMENS

The vulva was cleansed with pledgets of cotton saturated with saponated solution of cresol and a sterile bivalve speculum introduced into the vagina. With an

ordinary sterile teaspoon, material was scraped from the lateral walls of the vagina and deposited in a sterile Petri dish for subsequent transference to mediums. Additional material could be obtained from the anterior and posterior vaginal wall by rotating the handle of the speculum 45 degrees to the horizontal position. An average of 4 cc. of material was obtained.

METHOD OF CULTURE AND IDENTIFICATION

A portion of the specimen was planted in dextrose broth and incubated for from twenty-four to forty-eight hours at 37 C. Broth cultures which contained yeast cells were streaked on Sabouraud's dextrose agar and incubated for from twenty-four to forty-eight hours. Colonies on the Sabouraud's medium were smooth, round and white or cream colored, with a few specimens showing greenish discoloration. Microscopic observation of smears from typical colonies showed thick mycelium with terminal conidia.

The original broth cultures containing staphylococci and streptococci were streaked on blood plates and identified in this manner. Members of the colon-typhoid group and proteus group were identified by their reaction on Kligler lead acetate slants and Endo's agar. The diphtheroids, Döderlein bacilli and Micrococcus tetragenus were identified by direct microscopic observation of broth culture and the appearance of colonies on blood plates. No attempt was made to identify the various strains of these organisms, as we did not feel that such a study was pertinent to our purpose.

METHOD OF DETERMINING THE HYDROGEN ION CONCENTRATION OF VAGINAL SECRETIONS IN PREGNANCY

The hydrogen ion content was estimated by a modification of the Fenton "spot" method.¹ A drop of indicator was placed in the Petri dish near the vaginal specimen. By tilting the dish, the dye was brought into contact with the specimen. The color was compared with that of a buffer solution. The dyes most used were bromcresol green, bromphenol blue and chlorphenol red. The use of buffer solutions was abandoned about one quarter of the way through the series, and the colors were compared with the color chart reprinted from W. Mansfield Clark.¹

ANALYSIS OF RESULTS

In our series of 500 cases we found the monilia in fifty-four, an incidence of 10.8 per cent. Haussmann² found that 11 per cent of his patients had a yeast fungus and that the fungus did not necessarily produce symptoms. Von Winkel³ found mild mycotic vulvovaginitis in 4 per cent of 150 pregnant women. Woodruff and Hesselstine⁴ found the incidence of fungi in the vagina of women in the third trimester of pregnancy to be 28 per cent.

Of the fifty-four women in our series only five (9.2 per cent) complained of any discomfort. Each of these five complained only of pruritus. This finding supports Wong and Kurotchkin's⁵ observation that "it is not common for monilia to cause enough symptoms to make patients seek treatment." Fourteen (3.1 per cent) of the 446 women without moniliasis complained of itching and/or burning. Several observers have recorded that

1. Clark, W. Mansfield: *The Determination of Hydrogen Ions*, ed. 3. Baltimore, Williams and Williams Company, 1928.

2. Haussmann, David: *Parasites des organes sexuels femelles de l'homme et de quelques animaux, avec une notice sur le developpement de l'Oidium albicans* Rob, Paris, J. B. Baillière, 1875.

3. von Winkel, Franz: *Berl. Klin. Wchnschr.* 3: 237-239, 1866.

4. Woodruff, P. W., and Hesselstine, H. C.: *Am. J. Obst. & Gynec.* 36: 467-471 (Sept.) 1938.

5. Wong, Amos, and Kurotchkin, T. J.: *Monilia Vulvo-Vaginitis*, Chinese M. J. 48: 1058-1065 (Oct.) 1934.

the degree of local irritation varies greatly. Our patients complained only of pruritus. Smarting and burning and a feeling of dryness has been described, also pelvic fullness and vaginal sensitiveness. Often the symptoms are aggravated at night.

Castellani⁶ described two principal types of monilial vulvovaginitis: so-called "vaginal thrush," presenting white patches of membrane on the vaginal wall, the membranous type, and the purulent type, producing a thick purulent vaginal discharge. We noted none of the second type in our series of cases. Redness of the vaginal mucosa, introitus and labial mucosa is the sole finding in cases of mild involvement. In cases of more severe involvement the mucosa has a granular appearance and the vagina, cervix and occasionally the urethra are covered with a varying thickness, either in patches or in extensive membranes, of greenish yellow pasty adherent material, with an ooze of grayish watery material containing yellow flecks of mycelium. The pasty green accumulation can be partially removed with cotton or a spoon without causing bleeding, although vigorous removal from the granular upper part of the vagina was frequently associated with the appearance of pinpoint bleeding spots.

There were three cases of thrush in the newborn of this series, none of whose mothers had moniliasis.

Three patients (5.5 per cent) in the group with moniliasis were morbid: One had a cesarean section; another, with preeclampsia, abruptio placentae and fibromyomas, was operated on and the uterus removed, and the third had endometritis.

The morbidity in the group without moniliasis consisted of breakdown of an episiotomy scar in one case, mastitis in six, mild endometritis in twelve, an undetermined condition in four, cesarean section in six, thrombophlebitis in two, infection of the upper respiratory tract in two, scarlet fever in one and pyelitis in one. This is a total of thirty-five cases, or 7.8 per cent, a morbidity rate higher than in the group with moniliasis. Such authors as Crossen,⁷ Graves,⁸ Frank,⁹ Davis¹⁰ and Flusser¹¹ have expressed the opinion that *Monilia albicans* is pathogenic but that the infection is usually mild and does not occur often. Zweifel,¹² Stephan¹³ and Castellani and Taylor¹⁴ have said that they doubt the pathogenicity of the fungus.

Monilia was twice associated with *Staphylococcus aureus*, three times with diphtheroids and *Bacillus proteus vulgaris* and once with *Staphylococcus albus*, *Bacillus coli* and Döderlein's bacillus. In none of these cases was there any morbidity.

Kessler found the hydrogen ion concentration of the vaginal discharge to be between 4 and 5 during pregnancy. Oberst and Plass¹⁵ found it to be 4.76. In our series the range was found between 3.3 and 6.1, with an average p_H of 4.35. In the group with moniliasis it was essentially the same, 4.33.

We found the following organisms other than *Monilia albicans*: Döderlein's bacillus 279, diphtheroids

forty-eight, *Staphylococcus albus* 164, *Bacillus lactis aerogenes* two, *Bacillus coli* forty, *Staphylococcus aureus* twenty-six, *Bacillus proteus vulgaris* nine, non-hemolytic streptococcus six, *Streptococcus haemolyticus* three and *Micrococcus tetragenus* one.

Plass¹⁶ and his co-workers noted that the monilia disappeared from the vaginal tract soon after delivery. We observed that the vagina was essentially free in eight days and almost invariably clear within two weeks post partum. The lochial flow seems to exert a strong inhibitory effect on the fungus and to play an important part in causing its disappearance.

COMMENT

For the purposes of our investigation, identification of the various strains of the monilia or bacteria found was unnecessary. Jones and Martin¹⁷ have recently identified sixty-eight strains of yeastlike organisms from the vaginal tract of fifty-two pregnant women and sixteen nonpregnant women. They have developed an excellent technic for identification.

The same authors described a new species of monilia, the "stellatoidea." It is similar to *Monilia albicans*, and it may be of significance in the interpretation of certain clinical observations. It occurred in 43 per cent of their series and was shown to be nonpathogenic for rabbits. It may be a harmless parasite in the human vagina. The authors stated further that many of the yeasts formerly identified as *Monilia albicans* may prove to be *Monilia stellatoidea*. The presence of this yeast may not produce any subjective signs, and it may have been present in the majority of our cases.

Estrin is produced in excess during pregnancy, as is shown by the increased concentration in the blood and urine. It causes the vaginal mucosa to undergo marked proliferation. The cells are filled with glycogen, and there is an excessive desquamation of these cells. The glycogen is converted to lactic acid and the end result is a vaginal secretion with low p_H . Miura¹⁸ has estimated that the amount of titrable lactic acid increases from 0.4 per cent in early pregnancy to 0.9 per cent by the end of pregnancy.

Since an abundance of glycogen in an acid medium is an ideal environment for the growth of yeast cells, pregnancy provides an ideal opportunity for the growth of the monilia in the vagina. The recent excellent work of Davis and Pearl¹⁹ seems to substantiate this opinion.

SUMMARY

In a series of 500 cases of pregnancy we found the monilia in fifty-four, 10.8 per cent.

Only five of the fifty-four patients, 9.2 per cent, complained of any discomfort.

Three patients (5.5 per cent) in the group with moniliasis and thirty-five (7.8 per cent) of the group without moniliasis were morbid.

There was no morbidity in the group of patients who had other organisms associated with the monilia.

There were three cases of thrush in the newborn of this series. The mothers were in the group without moniliasis. Thus there would appear to be no important relation between these conditions. We found the p_H of the vaginal discharge to be 4.35.

AFTER-TREATMENT OF POLIO-
MYELITISK. G. HANSSON, M.D.
NEW YORK

When one turns back the pages of medical history and reads of the epidemics of the Middle Ages, one is struck by two things: the helplessness of the population and the superstition of the human mind. When an epidemic of poliomyelitis occurs today, the helplessness remains but the superstition has gone. Very little is known of the prevention of poliomyelitis. No specific treatment exists for the acute stage of the disease, but considerable progress has been made in the convalescent care of the residual paralysis. Statistics collected in Sweden between 1905 and 1937 showed 25,000 cases of poliomyelitis, 4,000 deaths and 10,000 cases of residual paralysis. This means that 40 per cent of the patients were left more or less physically handicapped and shows the reason for the dread of epidemics. Harry¹ of England has reported that 648 sporadic cases of poliomyelitis occur annually.

In this paper I shall confine myself to the discussion of the nonsurgical treatment required during the recovery period following an attack of anterior poliomyelitis. This recovery period is very long because one is dealing with disease of the nervous tissue. The nervous tissue is a highly specialized structure which recovers very slowly, and, when destroyed, the nerve cells cannot be reproduced or replaced.

The pathologic process in infantile paralysis is as follows: The virus enters the body through the upper respiratory tract and gains access to the spinal cord by the olfactory nerve. The virus attacks the anterior horn region of the cord, where the motor nerve cells are located, which innervates the skeletal muscles of trunk and extremities.

The after-treatment is based on the disease of the anterior horn cells. Microscopic examination of experimental animals and postmortem examinations lead to the belief that the degree of destruction can be classified in four forms:

1. Round cell infiltration and a transitory productive inflammation can produce enough pressure on the anterior horn cells to inhibit their function temporarily.
2. The horn cells may be starved by having their nutrition interfered with, either by a surrounding hemorrhage or a blocking of the small vessels that supply the necessary nutrition.
3. The virus may invade the nerve cell and injure it without destroying it.
4. The nerve cell may be completely destroyed, which means that there is permanent damage with no chance of recovery.

It seems only reasonable to believe that in cases of the first three types of lesions recovery will occur, and Dr. Bennett states that recovery takes place in cases of the first type in from two to sixty days and in cases of the second type in from sixty to 360 days but in cases of the third type in from three to five years.

Although the actual pathologic change in poliomyelitis is in the spinal cord and not accessible for inspection, one can judge by examining the skeletal muscles how much damage has been done. However, no conclusions can be drawn from such an examination as to the qualitative damage to the horn cells. No prognosis can

be given as to which muscles will recover and which ones will be permanently paralyzed. I believe that one should take an optimistic attitude and hope that all the muscles will recover. Therefore one should treat each muscle as a convalescent part going on to recovery and give it all the protection and care that are necessary for functional restoration. I know of no other disease in which the after-treatment is more important than in poliomyelitis, but before treatment is undertaken there must be a grading of the patient's muscles. This is done by a muscle test originated by Lovett² and still used with various modifications. Kendall's³ muscle grading, probably the most scientific, is shown in table 1.

MUSCLE REEDUCATION

Sir Robert Jones was one of the pioneers who advocated rest and protection for a paralyzed limb. After the epidemic of infantile paralysis in 1916, the most extensive one in the United States, during which in New York alone there were 10,000 cases, certain definite rules were laid down by Lovett.² They covered rest and protection, the clinical muscle and nerve test and muscle reeducation. Lovett,² Legg,⁴ Osgood and

TABLE 1.—Kendall's System of Muscle Grading

Percentage	Equivalent of	Test
0.....	Zero (0).....	No contraction felt in the muscle
5.....	Trace (Tr.).....	In a 5 per cent muscle a contraction is felt but there is no apparent movement of the part
10.....	Poor minus (P-)....	A 20 per cent muscle moves the part through a partial arc of motion with gravity eliminated
20.....	Poor (P).....	
30.....	Poor plus (P+).....	
40.....	Fair minus (F-)....	A 50 per cent muscle completes the whole arc of motion against gravity but may tire after from 3 to 6 movements
50.....	Fair (F).....	
60.....	Fair plus (F+).....

80.....	Good (G).....	
90.....	Good plus (G+).....	
95.....	Normal minus (N-)....	An 80 per cent muscle completes the arc of motion against gravity and a medium amount of resistance several times without showing signs of fatigue but tires quickly or is unable to complete the arc of motion against a maximum amount of resistance
100.....	Normal (N).....	
Contracted	Normal plus (N+)....	
		A 100 per cent muscle completes the arc of motion against gravity and a maximum amount of resistance several times without showing signs of fatigue

Wilhelmina Wright, all of Boston, deserve the credit for this early work. Boston was the fountain of knowledge for the treatment of infantile paralysis. About 1926, Lowman⁵ of Los Angeles began to experiment with muscle reeducation exercises under water. A great deal of emotional enthusiasm took charge of the crippled children. The federal government, the state, the county, the city and benevolent societies all over the country took a hand. Elaborate institutions grew up, with expensive equipment, and therapeutic pools reminiscent of oriental splendor were installed. I have visited crippled children's hospitals that cost close to a million dollars and had only about twenty patients. I have seen a beautiful pool in charge of uniformed nuns who blew their whistles and the children tumbled into the pool, where they played for fifteen minutes. Then the whis-

fles blew again and the so-called treatment was over. This emotional attitude was carried to such extremes that the patient with infantile paralysis became the spoiled child among the physically handicapped. In the enthusiasm for doing things for crippled children there developed an overemphasis on activities and neglect of two fundamental principles: the importance of rest and the protection of the weakened muscles.

These principles have always governed the treatment of drop wrist, drop foot and other forms of peripheral paralysis. The Kendalls of Children's Hospital School

of Baltimore have brought back the logical and rational view of the muscle reeducation of patients with infantile paralysis. They have emphasized the neutral or ideal rest position for protection of the entire body. In the protection of the body they included prevention of any stretching or strain of weakened muscles. This was accomplished by the wearing of protective supports, special care in handling the patient during nursing, and physical therapy. They also advocated restriction of the range of joint motion. Assistive movements were not allowed through the whole arc of function until the muscle was able to return actively to its shortened position. The Kendalls also advocated the use of heat, massage and pressure—suction treatment to prevent atrophy of the affected muscles.

Last winter I visited the Children's Hospital School in Baltimore and saw convincing results of the work done there, but I had hardly got back to New York when I came across another new idea in the treatment of poliomyelitis. It came out of Australia under the name of Sister Kenny's method. Mills⁶ reported that only thirty-five patients with the acute form have been treated but claimed the maximum improvement in 1,400 clinic cases. This treatment, used for twenty years, is based on the theory that the pain in the acute form is vascular in origin. The conception of the pathologic process is as follows: At first there is venous stasis. This is followed by capillary stasis and capillary paralysis. As a result mild trophic changes develop in the skin, the joints, the fascia and especially the muscles. Immobilization of paralyzed limbs increases the vascular deficiency, leading to contraction of muscle sheaths and anemia of muscle fibers and fibrosis. The acute form is treated with passive movements and hydrotherapy. The reeducation exercises begin within one week of the onset of paralysis. The restoration of circulation is accomplished by alternating sprays of hot and cold water. Here is a treatment exactly opposite to the one previously described. It disregards rest and immobilization and involves energetic treatment by contrast baths and by movement through every range of joint

every two hours. A finely graded system of reeducation exercises is started within the first week of paralytic manifestations.

I have presented two opposite views on the after-treatment of poliomyelitis. With the present conception of the pathologic process of poliomyelitis one must accept Kendall's contribution as the more rational one. The objections to his treatment are:

1. If the regeneration of a nerve axon is at the rate of 0.5 mm. daily, it will take twenty days to grow an axon of 1 cm., 200 days for 1 decimeter and 2,000 days, or more than five years, for 1 meter. To keep a patient in bed with muscle protection for five years is neither humane nor practical.

2. Such long inactivity can hardly be imposed on a child without some psychologic injury. I totally ignored the mental attitude of patients with poliomyelitis until three years ago, when I was called to see a girl of 17 who was living on a small farm in Connecticut. She had had poliomyelitis for two years and had been told that nothing more could be done for her. Her paralysis was slight but her mental attitude was that of a village cripple. I sent her to Warm Springs, Ga., and in six months she was walking without assistance, had regained her mental balance and had taken up art, for which she was well suited.

I fail to see the rationale of Sister Kenny's treatment, and it is difficult to subscribe to the conception of pathology on which it is based.

My own theory of the after-treatment of poliomyelitis lies somewhere between the extremes described. I believe that there is little or no difference between the treatment of poliomyelitis and any other lower neuron paralysis. There is but little disagreement as to the treatment of a dropped wrist due to radial nerve paralysis or a dropped foot due to paralysis of the anterior tibial nerve. In such cases one supports the weakened muscles, prevents any overstretching and maintains the nutrition and tone of the muscle by heat, gentle massage and reeducation exercises. I have on record a patient of 15 who had her right anterior tibial nerve injured in September 1937. She had paralysis of the extensors of the ankle and toes until January 1938, when she was given a leg brace that held the foot at 90 degrees to the leg. In February the extension of the ankle and toes had returned except for the big toe. The brace did not support the big toe, and a new brace was ordered

Number of muscles whose power increased to good (unbroken line), increased to fair (broken line) and remained poor (dotted line). It can be seen that the power of a maximal number of muscles increased to good in the four months period and that at six months the power of only half did so, while after a year the power of very few increased to good.

which included it. In another month extension of the big toe had returned, and April 15 the patient was discharged perfectly well. She had the same treatment before and after the application of the braces. This case shows convincingly how important it is to prevent overstretching of weak muscles. I believe that the greatest care should be taken to prevent unbalance between muscle groups which may lead to contractures and deformities. Any one who has seen the cold blue

6. Mills, F. H.: Treatment of Acute Poliomyelitis, Brit. M. J. 1: 168 (Jan. 22) 1938.

extremities of patients with poliomyelitis in northern climates must realize the importance of maintaining the nutrition and tone of the convalescent muscles. However, the circulatory deficiency is in all probability secondary to the paralysis and not primary, as reported by Dr. Mills in Australia and as Sister Kenny's method presupposes. The treatment I prefer for the circula-

had one upper extremity involved, two both upper extremities, twenty-seven one lower extremity, seven both lower extremities and seventeen the muscles of the trunk.

The first muscle chart that was used was made at least two months after the onset and therefore the initial spontaneous recovery was not included. The grading of muscles was done about every two months the first year and about every four months after that and as far as possible by the same technician.

In the calculation of the percentage of recovery, total paralysis was called zero and normal muscle 100. Any improvement from one grade to the nearest higher grade was therefore 20 per cent, and from zero to 100, or from total paralysis to normal, was 100 per cent. On the muscle-testing chart used nineteen muscles are listed in the lower extremity. Each muscle was tested, and the sum of the percentage of recovery of all involved muscles was divided by the number of muscles affected, which gave a percentage of recovery for the whole extremity. The upper extremities and trunk muscles were graded in a similar manner. Thus the sum of percentage of recovery was obtained which, when divided by the number of muscles involved, gave the percentage of recovery of the patient.

When this kind of calculation was applied in the twenty-six cases in which treatment was begun within six months of the acute onset, the actual muscle improvement taken as a whole was 29.07 per cent, and in twenty-eight cases in which treatment was begun six or more months after the onset the corresponding figure was 16.39 per cent. A comparison of the recovery of the various muscles shows that in the lower extremities the gluteus maximus, gluteus medius and dorsal flexors of the toes showed the greatest recovery and the tibialis anticus and posticus showed the least recovery. In the upper extremities the biceps showed a recovery of 80 per cent and the triceps the lowest recovery, or 29.5 per cent.

These figures correspond very closely to those of Harry. He made the statement that from four to six months after the acute onset one can determine the ultimate recovery, i. e. at six months it is possible to

tion is the application of paraffin and pressure-suction treatment. The muscle reeducation that I have employed is very much the same as that which Lovett and Wilhelmina Wright have described, and the exercises have been performed under water in a therapeutic pool with the temperature at about 92 F.

I am presenting in this paper a study of fifty-four cases of poliomyelitis from the epidemic of 1931 in New York City. The patients were treated under my direction at the Hospital for Ruptured and Crippled and at the New York Hospital. I was especially interested in comparing my figures with those of Harry.¹ I believe that the treatment of the two groups of patients was similar except that my patients were treated under water and Harry's patients were treated in a dry gymnasium. This study therefore represents the first comparison of underwater treatment versus table treatment using similar exercises or the new treatment versus the old one.

It is not an easy task to evaluate the recovery from poliomyelitis. Very few reports in medical literature actually show the benefit of the treatment. The most valuable report is that of Legg,⁴ who studied fifty-three cases and showed conclusively that steady follow-up treatment lasting even nine years is not only beneficial in preventing deformities but equally important in increasing muscle power. He also showed that the amount of improvement was in direct proportion to the attendance and the cooperation with regard to treatments.

The subjects for my investigation were patients who were admitted to the hospitals between 1931 and 1935 and were followed at least three years. Their only treatment consisted in underwater exercises in specially constructed therapeutic pools. They were not selected patients but consisted of children whom I was able to follow consistently, who were not operated on and who attended fairly regularly. Their average age was 8½ years. There were twenty-two boys and thirty-two girls. The extent of paralysis varied. Ten patients

TABLE 4.—Distribution of Paralysis

predict the ultimate extent of recovery. The majority of muscles which after six months were capable of moving the part, i. e. showed good, fair or poor function, developed useful contraction, while most of those that were not failed to recover. My figures corroborate this statement, and I think that it is of considerable prognostic value.

Harry's thirty-six patients were treated with rest in plaster during the acute stage and as soon as muscular tenderness had disappeared received heat, massage, electrical stimulation and muscle reeducation. My fifty-four patients also were treated with rest in plaster; about half of them were admitted for treatment when muscle soreness had disappeared and the other half about six months after the acute onset. The improvement in those admitted early was about twice that of

those admitted late. The treatment consisted solely of muscle reeducation exercises in the therapeutic pool. The distribution of paralysis is shown in table 4.

CONCLUSION

Ever since underwater exercises became popular about ten years ago, I have endeavored to compare the results thus obtained with the results that can be obtained in a dry gymnasium. I have often been asked by skeptical physicians if I had any concrete evidence of better results with underwater treatment than with other forms of treatment. I believe the comparison between my figures and those of Harry gives the answer: There is very little difference in percentage of muscle recovery.

I believe that the present consensus as to the after-care of patients with poliomyelitis is better protection of the weakened muscles and less indiscriminate activity. I should not be surprised to see the return of electrical stimulation to the weakened muscles, making the treatment of poliomyelitis similar to the care of traumatic peripheral nerve lesions.

What is then the advantage of underwater exercises? Should one continue to build more or less expensive therapeutic pools? The answer to these two questions is as follows:

1. The temperature of the pools ranges from 85 to 92 F., and thereby the application of heat, so necessary for the circulatory deficiency, is taken care of. Moist heat is better than dry heat, and the even distribution of heat through the contact of water is ideal. The heat will relax the muscles antagonistic to the weakened muscle group and thus prevent stretching of the paralyzed fibers.

2. The water obliterates the effect of gravity and keeps the weight of an extremity from overstretching the weakened muscle. The motion of the extremity through the water probably produces the best form of massage; manual application of massage may do much harm by excessive pressure on the capillary stasis.

3. The exercises can be performed with just as much care under water as on a table. With the gravity eliminated one has the same resistance to movements in all directions. The physician owes a great deal to the Kendalls for having recalled to him the importance of protection during and after exercises. Such protection can be observed in underwater exercises as well as in exercises out of the water. When the time for walking comes, this can be started more easily in the pool, even when crutches and braces are necessary.

4. Nothing can replace the therapeutic pool for the security that the patient feels when supported by the water. One is dealing with physically handicapped children who are very apprehensive of falling and doing harm to themselves. This fear is entirely eliminated in the water, and their morale, which is often low after a long illness, is boosted enormously. The pleasures of crippled children are few, and they look forward to their pool treatment with a great deal of interest and joy. The treatment in the dry gymnasium is monotonous and uninteresting, and I often use it as a punishment when the children do not behave themselves in the pool. Nothing explains better the psychologic effect of the underwater exercises than the plaque which was placed on the wall of the pool at the Hospital for the Ruptured and Crippled. It says "This pool is given to the physically handicapped children that in pleasure they may regain their health."

Clinical Notes, Suggestions and New Instruments

THE REMOVAL OF FOREIGN BODIES: A MODIFIED INCISION

CLARENCE E. REES, M.D., SAN DIEGO, CALIF.

The removal of foreign bodies such as needles, thorns and splinters which break off under the dermis at nearly right angles to the surface of the skin is sometimes complicated by difficulty in locating the object. This difficulty is due to the normal mobility of the underlying fat in which the foreign body is embedded and is made greater by the increased mobility of the fat when the incision is extended into it. As a result, the incision passes to one side of the foreign body so that the search must be extended into the walls of the incision instead

Fig. 1.—Usual incision: (a) foreign body in fat in normal relation to puncture wound; (b) displacement of foreign body to one side after usual incision.

of immediately beneath the cutaneous puncture where the object of the search should lie. Thus an incision into the fat immediately distorts the relationship between the puncture wound and the foreign body (fig. 1). Furthermore, in such mobile fat the exploring forceps may merely push the object ahead of them and displace it further. Under the fluoroscope foreign bodies that are opaque to x-rays have been seen to move ahead of the exploring forceps for a remarkable distance.

The fluoroscopic observation of the change of position of the foreign body due to this mobility of the embedding tissue has

Fig. 2.—Modified incision showing undercut edges of skin and displacement of foreign body into the wound. Inset shows relation of incision to puncture wound, the dotted lines representing undercut area.

led my associates and me to modify our incision in order to utilize this fat mobility to our advantage.

The modified incision extends only through the skin and is of sufficient length to permit the underlying fat to be cut away from the under surface of the dermis for a distance of one-fourth inch or more, the distance depending on the depth at which the foreign body lies. This undercutting is done immediately after the incision is made, care being taken not to incise the fat. The wound is then separated with the fingers and at the same time moderate downward pressure is exerted.

This maneuver causes the underlying fat to be extruded through the incision, carrying with it the foreign body, which then may often be lifted out without further manipulation (fig. 2).

In cases in which it is suspected that the foreign body is in contact with the under surface of the skin or when the puncture wound is obviously contaminated, an elliptic incision is made with the puncture wound as its center. The outer margins are undercut as before, and the underlying fat is displaced into the wound; when the ellipse of skin is removed, the foreign body can be easily located (fig. 3).

Fig. 3.—Elliptic incision for use in contaminated puncture wounds or in cases in which foreign body is in contact with skin: (a) relationship of incision to puncture wound with undercutting of margins; (b) after removal of central cutaneous area. Inset shows relationship of ellipse to puncture wound.

The use of this incision for the removal of foreign bodies makes it particularly important that certain precautionary measures be observed. The knife with which the incision is made should be very sharp, so that the depth of the incision may be controlled accurately; injection of the local anesthetic should be around and not into the area; in order that an increase of the bulk of tissue at the site of dissection may be avoided; and palpation for location of the object should be gentle so that the object is not displaced by it. If the foreign body is of an opaque nature a two way roentgenogram should be taken and a small marker placed at the point of puncture.

2001 Fourth Avenue.

RETROPERITONEAL RUPTURE OF A DUODENAL ULCER

S. F. LeBAUER, M.D., AND W. L. PATMAN, M.D.
GREENSBORO, N. C.

This case is of unusual interest (1) because of the diagnostic problem that presented itself and (2) because of the direction in which the gastroduodenal fluid drained. In a review of the literature no reference to a spontaneous rupture of a duodenal ulcer draining retroperitoneally could be found.

History.—A white man aged 39 of average height and rather thin, a clothing salesman, returned home one evening complaining of severe headache, pains radiating through the trapezius area and generalized aching with particular reference to the back. Thinking that he was suffering from influenza, he took a dose of castor oil about 10 p. m. Sleep overtook him until 5 a. m., at which time the bowels became obstreperous, watery elimination requiring attention on four occasions until 11 a. m. The last of these movements was dark but not black, according to the patient. He also stated that the entire abdomen became quite sore but reported no localizing pain. He drank liberally of fruit juices until about 4 p. m., at which time he vomited some orange juice. He then consented to call a physician (W. L. P.). This was twenty-four hours after the onset of the present illness. At this time his only complaint was soreness over the entire abdomen and aching in the right flank. The patient's past history was pertinent in that he referred to having had an ulcerated stomach some eight to ten years previously, though x-ray examination four and one-half years

before the present illness revealed no evidence of ulcer. Since that time he had been singularly free from symptoms referable to the stomach, despite eating a general diet and not infrequently imbibing whisky rather too freely on week ends.

Examination.—Symptoms and signs were centered about the abdomen and lumbar region. There was generalized tenderness over the entire abdomen, more marked in the lower quadrants and referred to both flanks (more marked on the right). The abdomen was soft with no spasm or rigidity. Tenderness was referred mostly to the right flank. The temperature was 99 F., the pulse rate 80, the respiratory rate 22. The impression recorded was intestinal influenza. Routine treatment for influenza was advised, i. e. an acetylsalicylic acid compound by mouth and a mustard plaster to the right flank. This night he was unable to retain the acetylsalicylic acid compound or any fruit juices or other liquids. One of us (W. L. P.) saw him the next morning and found him sitting up in a chair in what he considered his most comfortable position.

In view of the complexity and gravity of the patient's condition, Dr. LeBauer was called in consultation. At this time the patient appeared extremely toxic, with beads of perspiration on his forehead and an anxious expression. He had great difficulty in assuming the erect position. He walked in a flexed position, evidently splinting his right side. He was obviously in a great deal of pain. In bed he lay with his right leg flexed. General physical examination revealed that he was acutely ill. His skin was pale and covered with perspiration, his face drawn and his expression anxious (which in retrospect fitted exactly Dr. Moynihan's classic description of perforated ulcer). There was slight congestion of the nasal mucous membranes, and respirations were shallow with occasional sonorous and sibilant rales suggestive of an old chronic bronchitis. The respiratory rate was 30. The heart sounds were of good quality with no murmurs or arrhythmia and with a rate of 90. The abdomen was not distended but was somewhat scaphoid, with no visible peristalsis. There were marked spasm and rigidity over the entire right side of the abdomen, most pronounced in the right lower quadrant. Tenderness was so exquisite that the weight of the examiner's hand could not be borne. This tenderness extended back to the right flank, where there was questionable fullness. The temperature was 99 F.

A diagnosis of acute appendicitis with perforation was made. Only after much persuasion did the patient finally submit to hospitalization. On admission white blood cells numbered 19,000. The urine showed a faint trace of albumin with numerous hyaline casts and a few pus cells.

After routine preparations the patient was removed to the operating room, where under a general anesthetic a right McBurney incision was made; when the muscles beneath the fascia of the external oblique were separated, before the peritoneal cavity was entered, a large amount of thin flaky almost black watery fluid poured out (old blood?). The finger could be inserted into the retroperitoneal space as far as one could reach upward toward the kidney and posteromesially toward the vertebral column. The exposed muscle tissue appeared livid and greenish. The retroperitoneal space was packed with gauze to permit entrance into the peritoneal cavity. On exposure of the peritoneal cavity no free fluid was in evidence. The appendix was retrocecal but was lying free in the right gutter. It was delivered with comparative ease though slightly swollen throughout the distal half; its serous coat seemed definitely congested and the vessels were injected. It was removed in the usual fashion and the peritoneum closed. Two cigaret drains were inserted into the retroperitoneal space. The muscles, fascia and skin were loosely closed in the usual fashion.

The patient took the anesthetic poorly; his breathing was shallow and his pulse rapid and weak. As he was being removed from the operating table he vomited a large amount of light brownish flaky fluid (old blood?). Saline solution with 5 per cent dextrose was given intravenously at once and he responded very well. In less than an hour his dressing was saturated with the dark chocolate drainage material. About five hours after the operation about 8 ounces (240 cc.) of coffee

colored material was vomited. Profuse drainage continued, the dressing becoming saturated about every three hours.

On the second postoperative day the abdomen was soft; tenderness had disappeared and peristalsis was heard. Drainage continued unabated, its odor becoming foul; the abdomen appeared soft with tenderness confined to the right flank posteriorly. The rectal temperature ranged from 101 to 103 F., with the pulse rate from 80 to 90.

On the third postoperative day the patient reported that he was feeling well and craved liquids. One ounce (30 cc.) of water an hour was allowed; an enema was given which returned brownish green. Increasing amounts of water were permitted up to 3 ounces every hour. After water had been taken by mouth for approximately sixty hours the patient became nauseated and vomited copious amounts of a thin brown flaky fluid which gave a positive benzidine reaction. After this all fluids were administered parenterally, up to 3,000 cc. being given daily. Transfusions were given on alternate days. The drainage continued to be profuse and foul, and on the seventh postoperative day it appeared reddish at times. At this time a 5 grain (0.3 Gm.) tablet of methylene blue was given by mouth. The drainage material was stained blue within an hour, indicating a gastrointestinal fistula. The patient's condition grew worse and death occurred on the tenth postoperative day.

Autopsy.—This was performed by Dr. Maurice LeBauer.

The abdomen was flat. There was some feeling of fluctuation in the right loin beneath the muscle layers. A McBurney incision of recent origin was open with separation of the skin edges for its entire length and separation of muscle layers down to the peritoneum. From the wound a quantity of thin chocolate fluid estimated to be between 300 and 500 cc. was evacuated. By slipping the fingers into the wound beneath the muscle layers a separation of those layers from the peritoneum was found to extend upward toward the kidney region and beyond toward the midline in the retroperitoneal space. An incision to expose the contents of the peritoneal cavity was made. The omentum was adherent to the ascending colon for the proximal two thirds of its length on its lateral aspect, with fixation of the colon and attached omentum to the anterolateral parietal peritoneum. At the site of the adhesions the peritoneum of the abdominal wall, colon and omentum was discolored with blackish green pigment. The adhesions separated readily, but when the colon was pulled away from the lateral wall a rent was found in the parietal peritoneum, a communication thus being made between the peritoneal cavity and the retroperitoneal space, which was well sealed off from the peritoneal cavity by the adhesions described. In the region of the head of the cecum some omentum was adherent to the base of the recently removed appendix. A small abscess was located around the base of the appendix. A loop of terminal ileum contained some bloody fluid.

The rest of the omentum was neatly spread out as a curtain for the small intestine. There was no evidence of free peritoneal fluid or generalized peritonitis. On following the ascending colon up to the hepatic flexure, one encountered a mass of adhesions and inflammatory tissue. The hepatic flexure and the proximal portion of the transverse colon were adherent to the under surface of the liver. When it was stripped away the gallbladder was found surrounded by fresh adhesions connecting it to the duodenum. The gallbladder otherwise was normal.

The dissection was carried up along the lateral gutter on the right side, lifting the ascending colon, hepatic flexure and proximal transverse colon up from its attachment to the posterior abdominal wall. All the retroperitoneal space in the right half of the abdomen down to the level of the cecal head and mesially over the iliac vessels was dissected up by the bloody chocolate fluid. When the duodenum was exposed a perforation was found the size of a 5 cent piece (21 mm.) with sharp smooth edges and the mucosa rolled out into the opening. This perforation was later determined to be in the cap of the duodenum in its posterolateral aspect. The edges of the perforation were soft and sharply demarcated, and no surrounding border of scar tissue was found. The perforation opened retroperitoneally, probably as the result of adhesions

to the posterior parietal peritoneum, in the supramesocolic compartment, as evidenced by some leakage into the subhepatic region intraperitoneally. After removal of the duodenum and stomach it was found that the head of the pancreas formed part of the inflammatory mass at the site of the perforation and that the perforation lay about 0.5 cm. beyond the pyloric ring, extending for a distance of 2 cm. down the duodenum, which represented the diameter of the ringlike perforation.

COMMENTS

On the basis of the history and physical and laboratory examinations this case was interpreted as acute appendicitis, and the necessary surgical procedure for this type of lesion was done.

The first suggestion that everything was not as anticipated was encountered when the operator (W. L. P.) found a large amount of dark sanguineous fluid beneath the fascia of the right external oblique muscle. This was lightly regarded, however,

Autopsy specimen showing site of perforation in posterolateral aspect of duodenal cap 0.5 cm. beyond the pyloric ring.

in view of what was on gross examination considered a rather acutely inflamed appendix and in view of the absence of free fluid in the peritoneal cavity. It was felt that the patient's condition precluded further exploration.

Several times during the postoperative course we considered an exploratory operation, only to be discouraged by the condition of the patient. It became quite obvious that the appendix was not the whole story.

In a review of the literature no case of spontaneous rupture of a duodenal ulcer draining entirely retroperitoneally has been found. Eusterman and Balfour¹ in their monograph report three cases at the Mayo Clinic, all traumatic with 100 per cent mortality; Leibowicz² collected 176 cases, all traumatic.

Eusterman and Balfour report in cases of injury to the duodenum that when the rupture is confined to the retroperitoneal portion of the duodenum, which occurs in a third of

2. Leibowicz, M.: Subkutane Zwölffingerdarmverletzung, *Zentralbl. f. Chir.* 57: 1278-1283 (May 24) 1930.

the cases, the symptoms are comparable to those of ruptures of an ulcer into the lesser peritoneal cavity in that they may be so tardy or so mild and gradual in onset and progression that the gravity of the condition is not apparent. As Knaggs³ has said, even the most experienced surgeon has great difficulty in coming to an early conclusion that the abdomen ought to be opened. There is no communication with the free peritoneal cavity, so that tangible symptoms and signs of peritoneal irritation and inflammation are absent.

Eusterman and Balfour¹ report a case of traumatic injury to the right abdominal quadrant, following a kick by a horse, which simulated in many details the case that we are reporting: "extensive hematoma on the mesentery of appendix, cecum and entire ascending colon, but the bowel was of good color. No further surgical procedure appeared indicated except removal of the appendix." On the tenth postoperative day, jejunostomy was done for a duodenal fistula. The patient died several days later. Postmortem examination revealed traumatic rupture of the second part of the duodenum.

Eusterman and Balfour report that "occasional cases of rupture of the duodenum in which the patients have recovered have been reported in the literature. None of the patients who have been operated on for this condition at the clinic have recovered."

ANDROGENS AND THE "COLORING" OF WOMEN

E. C. HAMBLIN, M.D., AND W. KENNETH CUYLER, M.S.
DURHAM, N. C.

Dermatologic alterations are common in endocrine disease. Acne of adolescence and the hyperpigmentations of pregnancy are supposed to result from physiologic changes in the functions of the glands of internal secretion. Hamilton¹ and his group² have described characteristic alterations in the texture and pigmentation of the skin of surgically castrated and hypogonadal males following treatment with testosterone propionate. Hamilton and Hubert³ have related these pigmentational alterations to a "developing" action of the androgens on relatively colorless material laid down in the skin as the result of exposure.

In view of this apparent role of androgens in "developing" melanin, our observations on the urinary titers of androgens in normal white women seem significant when their "com-

Observations on Five Women

	Number of 24 Hour Specimens Titrated	Average Daily Titer Ex- pressed in Inter- national Units of Androsterone
Patient 1, blonde	19	14
Patient 2, moderate blonde	34	15
Patient 3, moderate brunette, fair skin...	36	21
Patient 4, moderate brunette, fair skin....	16	22
Patient 5, marked brunette, dark skin....	38	34

plexions" are considered. The average daily androgenic titers of true blondes have been found to be distinctly lower than those of marked brunettes.

Employing a colorimetric method for the determination of urinary androgens described by Oesting,⁴ we secured data on

five healthy white women, whose menstrual histories were normal, as shown in the accompanying table.

Similar correlations between the "complexion" and urinary titers of androgens have been observed by one of us (W. K. C.) in a much larger series of patients on each of whom a single specimen or at most several specimens were titrated for androgens by methods of bio-assay.

It is suggested that androgens may play an important role in the "coloring" of women and that individual variations in the degree of pigmentary alterations during pregnancy may be related also to characteristic differences in the metabolism of these sterols. Further studies may confirm these associations.

DILATION OF THE PUPIL FOR OPHTHALMO- SCOPIC EXAMINATION

LEO L. MAYER, M.D., CHICAGO

An ideal medicament to dilate the pupil in order to acquire knowledge of the optic nerve, the retina and the vessels has long been sought. Its characteristics would include comfort in application to the conjunctiva, rapid and complete dilatation of the pupil, absence of effect on accommodation, general toxic effects and tendency to increase the intra-ocular tension, and finally an action persisting not more than one or two hours. Using such a drug, the physician could readily examine the fundi without taking a long time and without inconveniencing the patient and could feel entirely satisfied as to any ultimate consequences.

After the isolation of epinephrine in 1901¹ and the realization of the activities of this substance, numerous attempts were made at its synthesis. Also interest grew in the possible value of compounds presenting similar basic structures, and in 1909 Barger and Dale² reported on a group of amines structurally related to epinephrine (3,4-dihydroxy α -phenyl β -methylamino ethanol). It was discovered that solutions of the salts of α -phenyl β -amino propane (amphetamine) had a vasoconstrictive potency equal to or greater than that of ephedrine (α -phenyl β -methylamino propanol).

I felt at that time that amphetamine sulfate might be the long sought ideal mydriatic, and studies made, to be detailed later, gave some promise. Later a related substance (4-hydroxy α -phenyl β -amino propane hydrobromide) was supplied.³ The close structural relationship of these two chemicals is shown by their formulas:

It is a well known fact that blue irises react to drugs more rapidly than do brown ones, the supposition being that because of the added layer of pigment in the brown irises the solution takes longer to reach the nerve endings and in addition the actual weight of the pigment makes the process slower.

The drugs commonly used to obtain mydriasis have been atropine sulfate, homatropine hydrobromide, scopolamine hydrobromide, cocaine, epinephrine, ephedrine, duboisine sulfate and eucatropine, all of which have some objectionable feature.

Atropine sulfate acts slowly and causes marked paralysis of accommodation, and its effect persists from ten days to two weeks.

Homatropine hydrobromide, scopolamine hydrobromide and duboisine sulfate, closely related to atropine, act similarly but are not so powerful.

Cocaine does not cause maximum dilatation and softens the corneal epithelium.

2. Barger, G., and Dale, H. H.: Chemical Structure and Sympathomimetic Action of Amines, *J. Physiol.* 41: 19, 1909.

3. Both the amphetamine sulfate and the 4-hydroxy α -phenyl β -amino propane hydrobromide solutions were supplied by the Smith, Kline and French Laboratories of Philadelphia.

Epinephrine and ephedrine act only in highly concentrated solution; their action is slow and persists for some days.

Eucatropine in a 2 per cent solution has been the best and most used for mydriatic purposes only. It causes dilatation in from forty-five to seventy-five minutes and produces partial paralysis of accommodation, and the pupil returns to normal in from four to eight hours.

This report concerns a comparison of the following solutions: (a) 2 per cent eucatropine, (b) 1 per cent aqueous (tear isotonic) amphetamine sulfate with 2.05 per cent boric acid, (c) 1 per cent aqueous (tear isotonic) 4,hydroxy α -phenyl β -amino propane hydrobromide with 3 per cent boric acid and (d) 3 per cent aqueous 4,hydroxy α -phenyl β -amino propane hydrobromide with 3 per cent boric acid.

Tests were conducted on patients in medical wards of Michael Reese Hospital and, through the courtesy of Dr. Theodore T. Stone, on patients in the neurologic ward of Cook County Hospital. Patients were selected as to age and the color of their irises. All were between 25 and 45 and the irises were either completely blue or dark brown. The size of the resting pupil was measured with a pupillometer without artificial illumination before instillation of the drug into the conjunctival sac and at various times afterward to the point of complete return to the original size.

It was ascertained that both pupils of each patient reacted normally and that no disease of the irises had been present, and the comparison was made by using one solution in each conjunctival sac. The four solutions were compared with one another. A summary of the results is given in the accompanying table.

A subjective test of ability to accommodate was made on all patients at various periods while the drugs were acting. The eucatropine solution caused blurring of close vision and inability to read readily for about three hours on an average. The other solutions caused no loss in accommodative effort. There was no rise in intra-ocular tension in any of the eyes examined. None of the solutions caused marked discomfort when introduced into the conjunctival sac; however, the stock solution of 2 per cent eucatropine frequently occasioned the complaint of a mild burning sensation. No general or local toxic effects were produced. This solution caused a persistence of the pupillary dilatation which averaged five and one half hours, while the periods for the other solutions were as follows: 1 per cent amphetamine sulfate one and one half hours, 1 per cent 4,hydroxy α -phenyl β -amino propane hydrobromide two hours and 3 per cent 4,hydroxy α -phenyl β -amino propane hydrobromide two and one half hours.

As a corollary experiment, with selected patients an attempt was made to cause the pupil to return to normal size by the use of antagonistic drugs. Those used were a 0.5 per cent

the 3 per cent solution of 4,hydroxy α -phenyl β -amino propane hydrobromide had been used, however, the pupil returned promptly to normal and remained so.

It may be concluded that, while a 3 per cent aqueous solution of 4,hydroxy α -phenyl β -amino propane hydrobromide does not fill all the requirements of an ideal mydriatic for ophthalmoscopic examination, it approaches them most nearly of all available drugs.

No discomfort is caused by 4,hydroxy α -phenyl β -amino propane hydrobromide, the dilatation is rapid and complete, and there are no general toxic effects. Accommodation is not perturbed, the intra-ocular tension is not changed and, finally, the dilatation is readily controlled.

In this investigation no correlation was attempted in the question of synergism for cyloplegia.⁴

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS.
HOWARD A. CARTER, Secretary.

THE BURDICK RHYTHMIC CONSTRICTOR APPARATUS ACCEPTABLE

Manufacturer: The Burdick Corporation, Milton, Wis.

The Burdick Rhythmic Constrictor is designed for the treatment of peripheral vascular diseases of the extremities by intermittent venous occlusion. It supplies compressed air alternately at predetermined time intervals to one or two pneumatic cuffs applied to the proximal part of the extremity under treatment. The unit is portable, weighs 20 pounds, is designed to operate on 50 to 60 cycles alternating current at 115 volts, and consumes 32 watts of current. An induction disk type, slow speed motor supplies the motive power and is directly connected to a small double-acting piston pump. This motor is noiseless and automatically adjusts its speed to the amount of pressure in the cuff.

The Burdick Rhythmic Constrictor Apparatus.

On the panel is mounted a selective timing device operated by a synchronous motor which automatically starts and stops the pump and deflates the cuff for predetermined periods. Six different periods of constriction and relaxation may be selected. A pressure regulator of a diaphragm type is also mounted on the panel by which the amount of pressure in the cuff can be regulated from 0 to 120 mm. of mercury and preset before the cuff is attached to the machine. A manometer on the panel registers the amount of pressure in the cuff in millimeters of mercury.

The cuffs are made of rubber and may be washed and sterilized. The pneumatic cuff for the leg is conical to fit the taper of the average thigh. Straight cuffs are also available for the arms. Valves to the air pump are automatically opened when cuffs are attached to the unit.

This unit is said by the firm to be indicated in frost bite, vascular diseases with major involvement of the large blood vessels, acute vascular occlusion and early thrombo-angiitis obliterans without extreme capillary stasis. Contraindications are given as thrombophlebitis, cellulitis, lymphangitis (acute or

Average Time for Complete Dilatation

Solution	Blue Iris	Brown Iris
2 per cent eucatropine	46 minutes	72 minutes
1 per cent amphetamine sulfate..	66 minutes	102 minutes
1 per cent 4,hydroxy α -phenyl β -amino propane hydrobromide	44 minutes	68 minutes
3 per cent 4,hydroxy α -phenyl β -amino propane hydrobromide	25 minutes	28 minutes

solution of physostigmine sulfate and a 1 per cent solution of pilocarpine nitrate. They were instilled immediately after the maximal dilatation had been reached. The physostigmine sulfate caused a rapid return to normal in all cases, and the contraction even went further. The miosis and ciliary spasm produced were much more of a discomfort than the dilatation of the pupil. The 1 per cent pilocarpine nitrate shortened the period of return to normal from dilatation caused by eucatropine from six to five hours. With the three other solutions the counteraction of the pilocarpine produced a normal pupillary size in one hour. However, when the pupils had been dilated with a 1 per cent solution of amphetamine sulfate or a 1 per cent solution of 4,hydroxy α -phenyl β -amino propane hydrobromide, the action of the pilocarpine continued, causing slight miosis, ciliary spasm and some blur for distance vision. When

Ophth. 21: 1019 (Sept.) 1938.

subacute), advanced thrombo-angiitis obliterans with capillary stasis, venous thrombosis and extensive destruction of the arteriolar or capillary vessels. The theory is that during venous constriction the venocapillary bed is filled and stretched, and when the constriction is relaxed a reactive hyperemia with vasodilatation occurs. This alternate constriction and release tends to increase the arterial flow in peripheral circulation during the release period.

The following effects are produced in organic peripheral vascular obstruction; (a) increase in blood supply, (b) relief of pain, (c) increase in skin temperature.

The firm submitted clinical evidence to show that the unit may be of value in the treatment of peripheral obliterative vascular disorders, arteriosclerosis and ulcers or lesions resulting from vascular diseases.

The unit was used clinically by a qualified physician on behalf of the Council and he reported that it functioned as well as similar apparatus already accepted by the Council.

In view of the foregoing report, the Council on Physical Therapy voted to accept the Burdick Rhythmic Constrictor for inclusion in its list of accepted devices.

FANGO di BATTAGLIA NOT ACCEPTABLE

Manufacturer: Fango Corporation of America, 239 East Forty-Seventh Street, New York.

Fango di Battaglia, as the name implies, is a mud from Battaglia, Italy, which is recommended for therapeutic use when applied in the form of mud packs. It is taken from the bottom of lakes fed by hot springs and is stated to be volcanic in origin. Dark gray, it is claimed to be free from gritty particles, roots and wood fiber, and consequently soft to the skin. Because of its volcanic origin, it contains more mineral than organic matter. The firm submits the following analysis of its chemical contents:

When the mud is dried, 49 per cent of water is lost, leaving behind 51 per cent of dry substance with a light gray appearance, which is very easily friable into an extremely fine powder. An analysis of this powder gives the following result:

	Per Cent
Water.....	56.4
Organic substances (including 1.92 per cent of humid substance and 0.28 per cent extractive by alcohol)...	6.43
Inorganic substances	89.93
	100.00

Of the latter, 42 per cent were dissolved by hydrochloric acid while 47.79 per cent were found to be insoluble.

The former consisted of:

	Per Cent
Carbon dioxide.....	11.75
Trioxide of sulfur.....	0.65
Siliceous earth.....	8.01
Phosphoric acid.....	0.21
Calcium oxide.....	12.04
Magnesium oxide.....	1.46
Oxide of iron.....	6.34
Oxide of aluminum	1.07
Oxide of potassium	0.23
Oxide of sodium	0.28
Manganese, sulfurated hydrogen, and volatile sebaceous acid traces	42.05

The firm claims that Fango is therapeutically effective because of its physical, chemical and radioactive properties. It is claimed to have beneficial effects on the skin, circulatory system, nervous system, metabolism, sweat glands and respiratory system. To support such claims, the firm submitted a bibliography of approximately 150 articles with brief abstracts for each.

When the submitted Fango was received, it was referred for investigation to a qualified physician. His report as adopted by the Council follows:

The object of these experiments was to evaluate the therapeutic possibilities of Fango di Battaglia and its advantages, if any, over other easily obtained, inexpensive and comparable topical applications. With this thought in mind, Fango was evaluated against Minnesota clay, common garden earth, paraffin, and paraffin and mineral oil.

The exploited factors of radioactivity and chemical make-up that would make Fango superior to other applications may be considered and discarded. The amount of radioactivity or emanation given off by this mud is practically negligible, as was easily proved by its inability to record on bromide photographic paper.

Chart 1.—Results of tests in small container.

Common knowledge of the physiology of the skin reveals that the various chemical substances in the mud will not be absorbed through the skin and cannot be expected to have any influence as a healing agent.

Thus it is possible to disregard the therapeutic effects of Fango's radioactivity and chemical constitution as healing agents in themselves. However, the mud's ability to retain heat is quite important therapeutically and bears closer study.

To test this heat-retaining property, the Fango was mixed with water (1 quart water to 3 pounds mud as outlined on direction sheet accompanying the product) and the mass placed in a double boiler and heated until it had an even temperature of 140 F. throughout. The inset container was then removed and set in a room of approximately 74 F. A thermometer was inserted and fixed so that its bulb was in the center of the mass. Readings were then made every ten minutes without disturbing the thermometers. The other substances used were treated in

Chart 2.—Results of tests in large container.

exactly the same manner. The results of the tests are seen in chart 1.

Chart 2 shows the results of a similar experiment, except that a larger container was used. This container permitted a larger cooling surface for the mud with a depth of about 2 inches, thus approaching the conditions existing in a therapeutic application, as over a human thigh.

It will be seen in chart 1 that Fango dropped from 120 to 100 F. (which may be considered the approximate limits of the therapeutic range) in ninety-five minutes. Garden earth closely

paralleled this drop in seventy minutes. Mississippi valley clay fell in fifty minutes. Paraffin and paraffin mineral oil dropped to 125 F. and 115 F. respectively and then maintained that temperature for the next two and one-half hours. This was due, of course, to surface solidification, which effectively insulated the center of the mass. Minnesota clay (sample from the Mississippi Valley also) and Fango were then treated as before except that a larger container was used. The rate of temperature drop was almost identical—the Fango in fifty-five minutes and the clay in fifty minutes (chart 2).

Application of the mud (Fango) was then made over a human thigh. A bulb thermometer was fastened to the surface of the skin over the midanterior aspect of the thigh by adhesive tape. The external portion of the bulb (that is, away from the skin contact) was shielded from direct contact with the mud by several layers of adhesive tape. The mud was then applied over the thigh to a depth of about $1\frac{1}{2}$ inches and covered by a rubberized sheet and several thicknesses of blanket. The calibrated end of the thermometer projected sufficiently to enable temperature reading without disturbing this application.

At the first application the mud was applied at 106 F. (limited to this height by subjective sensation). At the second application, the subject could tolerate 110 F. nicely.

Paraffin was used as a test control because it is an accepted method of applying topical heat in a routine test. It also proved

Chart 3.—Results of tests with Fango and paraffin.

itself an efficient heat insulator in the preceding experiment. The paraffin, unfortunately, could not be applied to a thick layer quickly, as could the mud. If the distal portion of an extremity had been used and the hand or foot dipped rapidly until a thick layer of wax had been built up, paraffin might have shown up to better advantage.

Chart 3 shows that Fango can be used to induce heat in a circumscribed area of body surface for a limited period of time if carefully surrounded by rubberized sheet and blanket.

It is not clear from our studies that this clay is sufficiently superior in its action to simple mud or clay to warrant its approval as a satisfactory material for the application of heat to various bodily areas.

One piece of advertising matter and several reprints were submitted with the products, a booklet "Fango di Battaglia." This contains several exaggerated, unwarranted or misleading claims. They include such statements as: "chemical and radioactive properties . . . determine its effectiveness"; "so-called bathfever . . . a resemblance to foreign protein therapy." It will be noted that many therapeutic indications are outlined in the latter part of the pamphlet. Critical evidence to substantiate the use of the mud in these conditions has not been submitted.

In view of the foregoing report, the Council on Physical Therapy voted not to include Fango di Battaglia in its list of accepted devices.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary.

IMMUNE GLOBULIN (HUMAN) (See New and Non-official Remedies, 1939, p. 412).

Lederle Laboratories, Pearl River, N. Y.

Immune Globulin (Human).—Placentas are selected in various hospitals from white women showing no sign of infectious disease and presenting a negative Wassermann reaction. The finely ground placentas are extracted with saline solution and the globulins are obtained from this extract by precipitation with ammonium sulfate. After removal of the salt by dialysis and addition of 0.05% of phenol, the globulin solution is sterilized by Berkefeld filtration. Marketed in packages of 2 cc. and 10 cc. rubber-stoppered vials.

BRUCELLA MELITENSIS VACCINE (See New and Nonofficial Remedies, 1939, p. 438).

The National Drug Co., Philadelphia.

Undulant Fever Vaccine (Abortus and Suis).—A heat killed suspension of *Brucella abortus* (bovine) 2,500 million per cubic centimeter and *Brucella suis* (porcine) 2,500 million per cubic centimeter, a total of 5,000 million per cubic centimeter. Merthiolate 1:10,000 is used as a preservative. The usual sterility tests prescribed by the U. S. government are made, and in addition blood agar streaks are made of the heat-killed vaccine before the addition of the merthiolate. Safety tests are made on the stock vaccine by injecting guinea pigs with the maximum human dose, 1 cc. No potency tests are made. Purity of cultures is determined by the study of colony formation, carbohydrate reactions and agglutination test with specific serum. The product is marketed in packages of one 5 cc. vial, in packages of one 15 cc. vial and in packages of one 30 cc. vial.

Dosage.—Deep subcutaneous or intramuscular injections of 0.1 cc., gradually increased by 0.1 or 0.2 cc., at three to five day intervals.

The National Drug Co., Philadelphia.

Undulant Fever Vaccine (Melitensis).—A heat killed suspension of *Brucella melitensis* (caprine) 2,500 million per cubic centimeter. Merthiolate 1:10,000 is used as a preservative. The usual sterility tests prescribed by the U. S. government are made, and in addition blood agar streaks are made of the heat-killed vaccine before the addition of the merthiolate. Safety tests are made on the stock vaccine by injecting guinea pigs with the maximum human dose, 1 cc. No potency tests are made. Purity of cultures is determined by the study of colony formation, carbohydrate reactions and agglutination test with specific serum. The product is marketed in packages of one 5 cc. vial, in packages of one 15 cc. vial and in packages of one 30 cc. vial.

Dosage.—Deep subcutaneous or intramuscular injections of 0.1 cc., gradually increased by 0.1 or 0.2 cc., at three to five day intervals.

ANTIPNEUMOCOCCIC SERUM, TYPE II (See New and Nonofficial Remedies, 1938, p. 399).

Mulford Biological Laboratories, Sharp & Dohme, Philadelphia and Baltimore.

Antipneumococcic Serum Type II, Refined and Concentrated-Mulford.—Prepared according to methods described by Lloyd D. Felton (*J. Immunol.* 21:357 [Nov.] 1931) from the serum of horses immunized by intravenous injections of virulent cultures of type I and type II pneumococci, and standardized for its content of type II antibodies. The potency of antipneumococcic serum type II, refined and concentrated, is expressed in terms of units and must contain not less than 1,000 units type II per cubic centimeter. By original definition a unit of antipneumococcic serum is that amount of serum necessary to protect mice against 1,000,000 M. L. D. of highly virulent pneumococci. Antipneumococcic serum type II, refined and concentrated, is tested by direct comparison of its protective value with that of a control serum, P11, issued by the National Institute of Health, which contains 150 units per cubic centimeter. Marketed in packages of one syringe containing 10,000 units, and in packages of one syringe containing 20,000 units.

ANTIPNEUMOCOCCIC SERUM, TYPE VII.—An antiserum containing antibodies of type VII pneumococcus (*Diplococcus pneumoniae*).

Dosage.—Intravenously, an initial dose of not less than 20,000 units followed by from 60,000 to 100,000 units in three doses at two hour intervals.

Mulford Biological Laboratories, Sharp & Dohme, Philadelphia and Baltimore.

Antipneumococcic Serum Type VII, Refined and Concentrated-Mulford.—Prepared according to methods described by Lloyd D. Felton (*J. Immunol.* 21:357 [Nov.] 1931) from the serum of horses immunized by intravenous injections of virulent cultures of type VII pneumococci and standardized for its content of type VII antibodies. The potency of antipneumococcic serum type VII, refined and concentrated, is expressed in terms of units and must contain not less than 1,000 units type VII per cubic centimeter. By original definition a unit of antipneumococcic serum is that amount of serum necessary to protect mice against 1,000,000 M. L. D. of highly virulent pneumococci. Antipneumococcic serum type VII, refined and concentrated, is tested by direct comparison of its protective value with that of a control serum, P7A, issued by the National Institute of Health which contains 900 units per cubic centimeter. Marketed in packages of one syringe containing 20,000 units.

THE CASE OF ASA BRUNSON VS. MORRIS FISHBEIN

On Monday May 29, in the District Court of the United States in and for the Western District of Texas, El Paso division, there came for trial before the Hon. Charles A. Boynton, a United States District Judge, and a jury the case of *Dr. Asa Brunson v. Dr. Morris Fishbein*. The plaintiff, Dr. Asa Brunson, was represented by Messrs. J. U. Sweeney and J. E. Quaid of El Paso, Texas, and the defendant, Dr. Morris Fishbein, was represented by Messrs. C. L. Harrell and H. D. Reynolds of Chicago and by Messrs. Brown & Brooke of El Paso.

As is usual in a federal court, the jury was selected from a panel of thirty who had been called, the attorneys being permitted to question the members of the panel on various subjects and then being permitted to strike off three names each, the remaining first twelve on the list being selected. There were then read to the court and to the jury the pleadings of the parties to the suit and the defendant's answer, after which the trial proceeded.

There is a new Federal Building in El Paso and the courtroom was a large, beautifully furnished chamber with provisions for an audience of several hundred. At various times during the trial the courtroom was taxed to its capacity.

In this case the plaintiff, Dr. Asa Brunson, who was treating tuberculosis with inhalations of a secret preparation, felt that he had been damaged because of a telegram sent by Dr. Fishbein to DeWitt Wallace, editor of the *Reader's Digest*. In January 1938 Mary Rose Bradford, wife of Roark Bradford, well known author, sent DeWitt Wallace a telegram asking whether or not he would be interested in an article dealing with the work of Asa Brunson, claiming that Brunson had cured more than 3,000 cases of tuberculosis and that he may be a second Pasteur. Mr. Wallace forwarded the inquiry to Dr. Fishbein, who telegraphed in reply that Dr. Hruby of the Chicago Municipal Tuberculosis Sanitarium had investigated the Holderness-Brunson treatment in 1921 and quoted from an article bearing Dr. Hruby's name which appeared in the Chicago *Herald and Examiner* stating that the method was a dangerous fake. To this quotation Dr. Fishbein added the statement that similar treatments tried elsewhere have also failed.

TESTIMONY OF DR. ASA BRUNSON

Direct Examination, Questions by Judge Sweeney:

Dr. Asa Brunson stated that he lived in El Paso, Texas. He is a physician and has resided in El Paso about fifteen and a half years. He studied at the Memphis Hospital Medical College from 1896 to 1899 and was graduated as a Doctor of Medicine and Surgery. After graduating he went to Wilmette, Ark., and practiced medicine there for a year and a half. He was admitted to practice under the laws of the state of Arkansas. Then he went to New Gascony, Ark., and remained until the 1st of January 1908. Then he went to Pine Bluff, Ark.

Q.—How long were you in Pine Bluff? A.—I was in Pine Bluff, actively practicing, until the 25th of September 1918, when I was commissioned as Captain in the army and was discharged from the army on the 19th of June or 21st of June, I have forgotten now which, 1919.

After his discharge from the United States Army he resumed practice in Pine Bluff, Ark., and practiced until the 5th of March 1921, when he went to El Paso. He arrived on March 7, 1921. He came to El Paso to use the Holderness treatment for tuberculosis. He was admitted to practice in the state of Texas Dec. 15, 1923. He was connected with Holderness from about Oct. 1, 1920, in Pine Bluff, Ark., until some time in March 1922, in El Paso. He then bought the medicine from Holderness and practiced in El Paso; "that is, I gave the medicine, I had a doctor, until about the 10th of May, 1922, then I sold the furniture to the doctor and left."

Q.—What doctor? A.—Dr. S. T. Harris.

Q.—Where is Dr. Harris now? A.—I don't know.

Q.—Was any other doctor connected with you here? A.—While I was here? Yes, we had Dr. Bolling at first, and Dr. Thomas.

Q.—Where is Dr. Bolling? A.—Dr. Bolling is dead.

Q.—Where is Dr. Thomas? A.—Dr. Thomas is in Houston, Texas.

Q.—How long was Dr. Thomas associated with you? A.—Dr. Thomas was associated with us about three months.

Q.—State the relationship between yourself, Dr. Thomas and Holderness. A.—Dr. Thomas was an employed physician, because we didn't have a license.

Q.—Who employed him? A.—I employed him.

Q.—Individually? A.—I employed him individually.

Q.—Am I talking loud enough for you? A.—Yes, I can hear most everything you say.

Q.—What was the purpose of his employment? A.—The purpose of his employment was so that we could give the treatment according to the laws of the state of Texas.

Q.—What did he do? A.—He examined patients and prescribed for them.

Q.—How long was he connected with you? A.—About three months.

Q.—Then what happened, after the expiration of three months?

A.—After the expiration of three months, we employed Dr. S. T. Harris for the rest of the time that I was in El Paso.

Q.—Did Dr. Thomas resign or quit the employment? A.—Well, I suppose he called it resigning, I didn't want him any more.

Q.—You were paying him how? A.—What?

Q.—How were you paying him? A.—Paying him \$250 a week.

Q.—And he practiced merely with you, not on the outside? A.—He went to see patients that weren't able to come to the office, and examined and prescribed for patients in the office.

Q.—What was the occasion of his stopping his employment with you? A.—Well, I think the main reason was that he stated that Holderness wouldn't give up his formula.

Q.—Any other reasons? A.—Yes, it caused him to get fired out of the medical society.

Q.—Where? A.—Here.

Q.—After that, how long were you connected here with Holderness? A.—You mean after Thomas left?

Q.—After he left. A.—I made an arrangement with Holderness some time in March 1922 to buy the medicine from him and I would run the business myself, and on or about the 10th of May I sold out to Dr. S. T. Harris and left, and I have never used the Holderness treatment since.

Q.—What year was that? A.—1922.

Dr. Brunson then testified that he went to Little Rock, Ark., and stayed for five weeks, then to Chicago for five or six weeks and then back to Little Rock, Ark., where he opened offices, remaining until Jan. 13, 1924. Then he went to El Paso, Texas. In Little Rock, Ark., he had been treating tuberculosis with his own remedy, which was not connected with the Holderness remedy. He stated that he had never known the Holderness formula and had never divulged it. The testimony then proceeded:

Q.—What is your theory in the practice of medicine for the treatment of tuberculosis? A.—You just want the whole theory?

Q.—Your theory. A.—The reason I began treating tuberculosis was because I determined that the pus germ was doing the most harm, the absorption of pus causing every bad symptom that was manifested, and I thought if something could be given by inhalation that wouldn't irritate the lung or cause a harmful reaction that it would be a good treatment. I began using that after I discontinued with Holderness. I was working on my formula when Holderness told me one day, when he came in my office, that his father had a formula that was given by inhalation and that it was good. I knew Dr. Holderness by reputation, so I told Dr. J. S. Holderness to make me up a bottle of that medicine and I would try it out, I wasn't afraid to try it. I tried it at that time and I got good results. The people in Pine Bluff are, like many places, away from tubercular centers, they were afraid of tuberculosis, and I was asked to give up my offices or stop having tuberculars come to see me. That was then Holderness and myself decided we would come to El Paso. I had thirty-five or forty patients, and I got Dr. Simmons of Pine Bluff to look after those patients for, oh, two months after I left here—I mean left Pine Bluff.

Q.—With reference to tuberculosis, state whether or not the tubercular germ is in all human beings? A.—That is a common opinion of the best doctors, that every one has the tubercular bacillus in their system.

Q.—What creates tuberculosis? A.—The tubercular bacilli.

Q.—How? A.—By causing an irritation of the lung; but, without the mixed infection, it would never do but very little harm.

Q.—Then it is your theory that all human beings have the tubercular germ in their system? A.—That is my opinion.

Q.—And that it is when an individual is run down an irritation takes place in the lung, pus forms, that they become tubercular? A.—Well, they are already tubercular, before they have the mixed infection.

Q.—What do you mean by mixed infection? A.—The pus germ. That was responsible for every death we have ever had from tuberculosis.

Q.—Then it is your theory to remove the pus? A.—Remove the pus and you prevent patients from absorbing the poison that they had been absorbing; and when you can keep that eliminated, you give nature an opportunity to build your patient up, and nature is the only doctor that we really have, medicine is indicated to aid nature only.

Q.—Now, Doctor, what are the manifestations of tuberculosis? A.—You mean the symptoms they usually have?

Q.—Symptoms, I may have used the wrong word. A.—It begins a little differently with different people. The usual rule is they begin with a slight cough, they lose in weight, lose their appetite, soon begin running a temperature, then begin coughing up mucus and pus. We put some of the expectoration under a microscope and we find the tubercular bacilli, in some cases we never find it, that is the proof positive of tuberculosis, the finding of the tubercular bacilli in the sputum.

Q.—What other physical effects manifest themselves?

A.—Well, just as the Bible said in the laws of Moses, it is a wasting away.

Q.—They have temperature?

A.—They run temperature for some time after a person has had tuberculosis, say from eight months to two, three or four years. Many of them discontinue running temperature; the temperature out here in this country runs subnormal.

Q.—Then your theory is to remove the pus from the lung?

A.—That is the only thing that has ever gotten any beneficial effect in the way of medicine.

Q.—How long have you specialized in tuberculosis?

A.—Since the fall of 1920.

Q.—Now, during that length of time, how many patients, approximately, have you treated, since the fall of 1920?

A.—That would be rather hard to approximate, I would say about two thousand.

Q.—What has been your degree of success with them?

A.—Patients who have stayed with me and taken treatment as long as I would want them to take it, to be sure that they were well, I believe I have cured about 60 per cent; I have benefited about 90 per cent.

Q.—What do you mean by cured? A.—I mean that they have no symptoms whatever of tuberculosis.

Q.—Have you had those patients examined both before and after your treatment? A.—Many of them.

Q.—And the x-ray has shown a healing of the lungs? A.—Yes. It shows old scars. If you have had pneumonia or tuberculosis any length of time, it always shows scars after you are well.

Q.—Doctor, in 1921, approximately, I forget whether June or July, did you meet a Dr. Hruby? A.—Dr. Hruby was here in July or August 1921.

Q.—State your contact with him and what happened. A.—Dr. Hruby came to our office about 9 or 9:30 one morning.

Q.—Who is "our" office? A.—Holderness and Brunson. He came to the office and said that he came down to investigate the treatment. I told him we were very glad to see him and that an investigation was just what we wanted. He examined four or five patients in the office. Right after noon I took him out to see a Mr. Martin on Aurora Street. He talked to him a few minutes, he didn't examine him, and we left and came back to the office. About 5 o'clock, when we were closing, I told Dr. Hruby we would see him the next morning; he says "I am going back to Chicago tonight." I said "Doctor, you haven't been here long enough to tell what the effect of calomel

would be." I said "You made up your mind you were going to condemn the treatment before you left Chicago." He says "I don't know about that," he says "I have to go back to Chicago." Whether he left that night or not, I don't know, he was never in our offices but that one time.

Q.—Did he have a sample of your medicine? A.—No.

Q.—Did he see any patients treated? A.—He saw some patients treated, I think he took a treatment himself, and he is still living.

Q.—How long, then, were you in contact with Dr. Hruby or knew that he was here? A.—I didn't know that he was here until he came to the office about 9:30 one morning, and that day was the only time that I ever saw him.

Q.—And what formula was it you were treating under at that time? A.—It was the Holderness formula.

Q.—How long after that was it that you commenced the treatment under your individual formula? A.—It was the next year, about the 1st or 2d of July 1922.

Q.—Did Dr. Hruby come down here and examine that at that time? A.—No, he came down in '21.

Q.—He was never here afterward that you knew of? A.—He was never here afterward that I ever heard of.

Q.—You say you have been specializing since about 1920? A.—Since about the 1st of October 1920.

Q.—When did you get your Texas license to practice medicine? A.—On the 15th of December 1923.

Q.—And you started practicing in January 1924 in El Paso? A.—I started practicing here on the 15th day of January 1924.

Q.—And I understand, from the time you left El Paso in 1921, after you— A.—I left here in 1922.

Q.—After you dissociated yourself from Holderness, that you did not use your formula here in El Paso until 1924? A.—Yes, that is right.

Q.—You did use it in Arkansas? A.—I used it in Little Rock.

Q.—Doctor, how do you arrive at the therapeutic value of medicine or a formula? A.—No doctor or chemist can arrive at a positive conclusion without trying the medicine out; drug using is drug proving.

Q.—It is a course of treatment? A.—You have to treat a patient, under the observa-

tion of a competent doctor, for a certain length of time to determine whether it is beneficial or inert.

Q.—In tuberculosis, how long would it take to ascertain the therapeutic value of a medicine? A.—That would a great deal depend on the time that a patient has had tuberculosis, what their resistance is, but, I would say in ninety days that any one could tell that the treatment was beneficial.

Q.—Whether it was beneficial? A.—That my treatment is beneficial, they could tell in ninety days.

Q.—The ordinary treatment, any treatment for tuberculosis? A.—It has to be tried before you can determine whether it is worth anything or not, and no medical treatment has ever been found that was worth anything.

Q.—That means a course of several weeks or several months? A.—Several months. I believe a tubercular specialist would state he would take about two years to fully determine whether a patient was well or not.

Q.—I am speaking of determining the therapeutic value? A.—You mean beneficial or cure?

Q.—The therapeutic value of a formula. A.—Oh, you can tell the therapeutic value, by the improvement of your patient, in ninety days.

DR. ASA BRUNSON

Q.—It would take a course of time, however, to determine the therapeutic value? A.—Yes.

Q.—The therapeutic value of a formula or a medicine could not be determined in twenty-four hours? A.—Absolutely not, it couldn't be determined in three or four weeks.

Q.—Can a chemist determine the therapeutic value—

Mr. Brown:—Judge Sweeney's questions all along have been leading and suggestive, we object and ask him to discontinue.

The Court:—Don't ask leading and suggestive questions.

Judge Sweeney:—I will seek to do that.

Q.—Now, Doctor, are you acquainted with Dr. Morris Fishbein? A.—No, I am not.

Q.—Ever met him? A.—Never have met him.

Q.—Ever communicate with him? A.—I have written letters to the A. M. A. and I have had a letter written to him, but he never has written to me.

Q.—He never replied to your letters? A.—I never got any replies to the letters I wrote to the A. M. A. in regard to scientific investigation of my treatment. I offered to pay for an investigation.

Mr. Brown:—We object, unless he shows in what form that offer was made and what it was, we object to it. He never saw Dr. Fishbein personally; it, therefore, must have been in writing, we object to it as secondary evidence and not the best evidence.

The Court:—It is not responsive; the Court sustains the objection. If it is in a communication, the letter is the best evidence.

Mr. Sweeney:—If it please the Court, we want to introduce a copy of the telegram in question. In their answer they have admitted sending the telegram, and I want to just offer a copy of it for the record.

The Court:—You are now referring to telegram sent by whom to whom?

Mr. Sweeney:—By Fishbein to DeWitt Wallace.

The Court:—That is set up in the pleadings and is admitted.

Mr. Sweeney:—If it please the Court, I want to put it in. I presume it is a wire from DeWitt Wallace to Morris Fishbein. May I read that to the jury?

Mr. Brown:—The DeWitt Wallace deposition contains an exact copy of the whole thing. That would be better. Then there wouldn't be a duplication.

The Court:—It is set forth in the pleadings and admitted. Read it out of the petition unless there is some question about the correctness of that copy.

Mr. Brown:—The only point about it is this, just before the body of the telegram, the original shows what was said in response and positively identifies it.

Mr. Sweeney:—It reads: "Dr. Morris Fishbein. American Medical Assn. Chgo. Please advise wire collect or air mail what you think of following statement quote Dr. Asa Brunson of El Paso Texas has been making quiet but remarkable cures of pulmonary tuberculosis with formula used in atomizer or nebulizer and sprayed into lungs by inhalation three thousand cures in twelve years patients are flocking to El Paso to be cured within six months Dr. Brunson has begged U. S. Surgeon General for hundred patients for simultaneously treatment with hundred treated in usual way with monthly examination but no go stop Brunson is licensed M.D. and comes from a long line of American physicians he may be another Pasteur and a prophet without honor unquote. DeWitt Wallace Reader's Digest."

The Court:—What is the date of that telegram?

Mr. Sweeney:—19th day of January 1938. Here is the telegram in response to that telegram: "Mr. DeWitt Wallace. Reader's Digest. Mt. Kisco, N. Y., or Pleasantville, N. Y. Brunson cure investigated nineteen twenty-one by Allen Hruby comma Medical Superintendent Chicago Municipal Tuberculosis Sanitarium stop he says quote treatment without value as specific or cure for consumption stop in my opinion it is a fake of the most dangerous kind unquote treatment involves inhalation of menthol comma eucalyptol and turpentine stop similar methods tested elsewhere have also proved to be failures. Morris Fishbein." I want to introduce the telegram that was sent to Mr. DeWitt Wallace that occasioned his telegram to Dr. Fishbein "El Paso, Texas, January 19, 1938. Mr. DeWitt Wallace. Reader's Digest. Pleasantville, N. Y. Are you interested in article about Dr. Asa Brunson of El Paso Texas who has been making quiet but remarkable cures in pulmonary tuberculosis with formula used in atomizer or nebulizer and sprayed into lungs by inhalation three thousand cures in twelve years patients are flocking to El Paso to be cured within six months Dr. Brunson has begged U. S. Surgeon General for hundred patients for simultaneously treatment with hundred treated in usual way with monthly examination but no go stop Brunson is licensed M.D. and comes from a long line of American physicians he may be another Pasteur and a prophet without honor stop we are here for a couple of weeks spent Christmas in Santa Fe wire me Hotel Del Norte. Mary Rose Bradford."

This is the letter from Dr. Fishbein to Altheimer.

Mr. Harrell:—That letter is in response to something. He would not write that without having received something.

Mr. Quaid:—We reserve the right to introduce that as we see fit.

Mr. Harrell:—You have the other letter have you not?

Mr. Sweeney:—This was admitted in their answer. That is what I am reading: "The Journal of the American Medical Association. 535 North Dearborn Street Chicago. Editorial Department. Morris Fishbein, M.D. Editor. (In your reply please refer to these initials: MF.) February 7, 1938. Mr. Ben J. Altheimer, Chicago, Illinois. Dear Mr. Altheimer: I am still convinced that the promotion as a cure for tuberculosis of a solution such as that used by Brunson in a nebulizer is a dangerous form of practice. If Doctor Brunson wishes his treatment investigated by the American Medical

Association all that he needs to do is to reveal his formula and to make due application to the Council on Pharmacy and Chemistry of the American Medical Association. Very truly yours. Morris Fishbein."

That was in response to this letter. I will not read the heading on the letter: "Dr. Morris Fishbein. 535 North Dearborn Street. Chicago. February 3, 1938. My dear Doctor: This morning I received a letter from Dr. Asa Brunson of El Paso, Texas, who is specializing in the treatment of tuberculosis. Dr. Brunson is a boyhood friend of mine from my old home in Arkansas . . ."

Mr. Brown:—We are going to object to that, if your Honor please. We except and object to the introduction of that letter at the present time because it has not been properly identified or proven up, and, furthermore, it contains statements that, at least, would not be admissible at this time. It is hearsay.

Mr. Sweeney:—I did not intend to introduce it in the first place. I was merely proving up what they admitted in their petition. I did not desire to offer it or urge it.

The Court:—Do you withdraw it at this time?

Mr. Sweeney:—Yes, sir, we withdraw it.

Q.—Now, Dr. Brunson, after you became cognizant of the letters that have just been introduced here, what effect, if any, did that have upon you? A.—It had a very depressing effect upon me. It made me feel that I was incompetent, that I was a faker, that I was giving people a dangerous treatment and it made me feel terribly bad.

Q.—How does it affect you now, Doctor? A.—The same way.

Q.—If you can, state how has your practice been affected, if it has been affected?

Mr. Brown:—If Your Honor please, I think that calls for a very general, broad statement, too general, too broad. It calls for conclusion. We object to it.

The Court:—The Court sustains the objection. If the practice has been affected, of course, it can be shown by some positive evidence, showing some special damage. The Court sustains the exception.

Q.—Dr. Brunson, prior to this, in prior years what has been the extent of your practice as a tuberculosis specialist? A.—It has gotten less every year.

Q.—Since about when? A.—It started in '31.

Q.—How was it prior to the publication of this? A.—After it was published in *Hygeia* . . .

Mr. Brown:—If Your Honor please, there is no reference to publication in *Hygeia* or when the publication was made in *Hygeia*. We object to that unless that information is given, and unless it is within one year prior to the suit, we object to that.

Mr. Sweeney:—I think Mr. Brown is correct as to that.

The Court:—Very well.

Q.—Doctor, I asked the question how it has been affected since this telegram, if it has been affected. A.—Repeat that question.

The Court:—The date was February 20, 1938.

Mr. Brown:—The question as to how his practice has been affected since the receipt of that telegram is too general in its nature, not specific enough and we object to it.

The Court:—The question is very general. If you could show a specific damage it could be confined to that. There are a good many reasons why a practice might be decreased and increased regardless of telegrams.

Mr. Brown:—We suggest that might be reached by asking for certain things.

Mr. Sweeney:—I know how to reach it. I do not need any suggestions.

Q.—Dr. Brunson, what has been the extent of your practice since February 1938? A.—I have very little.

Q.—What do you mean by very little? A.—I haven't a pay patient coming into the office today.

Q.—How long has that been a fact? A.—It has been off and on for the last year or since we got that telegram.

Q.—This case has been pretty generally discussed here in the city? A.—Yes.

Q.—People know about it?

Mr. Brown:—He is now talking about a case, having brought a lawsuit.

Mr. Sweeney:—I withdraw that question.

Q.—You state, Doctor, that you did suffer pain, humiliation, embarrassment by reason of the publication of that telegram? A.—Yes.

Q.—Doctor, this telegram that I read a while ago from DeWitt Wallace to Mary Bradford, stating what Dr. Fishbein had stated in his telegram to DeWitt Wallace, you received from whom? A.—I have forgotten who she gave it to, she gave it to some one to give to me. I didn't know who that was.

Q.—This reached you? A.—Yes.

Q.—How did you construe the words "dangerous fake"?

Mr. Brown:—If Your Honor please, how he construes it is immaterial. We object to it.

The Court:—The Court sustains the objection.

Q.—Doctor, is your medicine dangerous? A.—Absolutely not.

Mr. Brown:—We object to that, if Your Honor please.

The Court:—The Court overrules the exception. He is a doctor, he is an expert and will be permitted to answer that question.

Mr. Brown:—We except.

Q.—Is your medicine a fake? A.—No.

Q.—In your experience in using your medicine during the last—Since 1922, since you have promulgated your formula, what has been your experience with it with reference to its therapeutic value? A.—It has wonderful therapeutic value, else I never would have given it.

CROSS EXAMINATION

By Mr. Brown:

Q.—Dr. Brunson, your first schooling was in a medical school?

A.—Memphis Hospital Medical College.

He then testified that he went to the University of Tennessee, Maryland Military and Naval Academy and to Belleview, Va., at the W. R. Abbott School, a semicollge, where they had preparatory classes and advanced classes. He first went to school at a Convent in Pine Bluff, Ark., about a year and a half, and then had a "governess on our plantation," for three or four years. Next he went to the Maryland Military and Naval Academy from about the middle of May until the next March.

Q.—It is no longer in existence? A.—No, it broke up. That was the reason I left there.

After Belleview he went to the University of Tennessee.

A.—I went there the first part of September and on account of my father's illness I left about the middle of May 1890.

Q.—Then you were out of school for a long period of several years, were you not? A.—You mean before I began studying medicine?

Q.—Yes. A.—From 1890 I was out about six years.

Q.—And were clerking around, bookkeeping? A.—Mostly bookkeeping.

Q.—What did you do in that intervening period of years? A.—Those six years?

Q.—Yes. A.—I worked for a while in Dallas, Texas, and I worked in Memphis, and I worked down in Mississippi.

Q.—What was the general nature of your business during those years? A.—It was accounting business.

Q.—And clerical? A.—Yes.

Q.—Then what did you do? A.—I studied medicine.

Q.—What branch of medicine? A.—They taught all branches.

Q.—How long was each session? A.—About seven months.

Q.—Then you attended three sessions of seven months each? A.—Three sessions.

Q.—You say you graduated from there? A.—Yes.

Q.—In what year? A.—I graduated on the 27th day of April 1899.

Q.—And when were you licensed in Arkansas? A.—We had county boards at that time and I think it was about the 10th of May I was admitted to practice.

Q.—Was this college in Memphis run in connection with a hospital? A.—You mean the Memphis college?

Q.—Yes. A.—Yes, run in connection with the City Hospital.

Q.—And the only medical education you had was that which you received at this hospital college? A.—That is about all that any doctors get.

Q.—I am not asking you that. I am asking you if that was the only medical education you received? A.—That was the only medical education I received.

Q.—When did you first meet Jim Holderness? A.—That is rather a hard question to answer. I have known him from boyhood. I don't remember just when I did first meet him.

Q.—Isn't it true he was never a licensed practitioner of medicine? A.—He never had a license to practice.

Q.—He was unable to obtain a license in Arkansas, wasn't he? A.—He was unable to obtain a license in Arkansas?

Q.—He was unable to obtain a license in Arkansas, wasn't he? A.—I didn't know that until I saw his deposition.

Q.—That is true, isn't it? A.—I guess it is for he said so.

Q.—He never took out a license in Texas? A.—No, he never did.

Q.—You and he though operated together in Arkansas for how long a period of time? A.—Well, he furnished the medicine; he didn't very seldom come to my office at all—from about the 1st of October until we left there on the 5th of March '21.

Q.—The 5th of October 1920? A.—1920, yes, sir.

Q.—Until March 1921? A.—Until March '21.

Q.—You were using his remedy during that period of time?

A.—I was using his remedy in Pine Bluff, Ark.

Q.—Did you and he both come to El Paso at the same time? A.—We both came down together.

Q.—And opened up offices in what building? A.—In what building? Well, it was called the El Paso Bank & Trust Company Building at that time. It is the Abdou Building now.

Q.—On the corner of Texas and Mesa? A.—Yes, sir.

Q.—How long were you in that office? A.—We were in that building the entire time that we were here.

Q.—You had on the doors Doctors Brunson & Holderness, did you not? A.—We did not have anything on the door at all.

Q.—Are you certain about that? A.—I know it.

Q.—Have you read Jim Holderness's deposition? A.—No.

Q.—You say there was nothing on the doors at all? A.—Never did put anything on the door.

Q.—You held yourselves out as administering what was known as the Brunson-Holderness treatment for tuberculosis? A.—The Holderness treatment; not Brunson.

Q.—You say you haven't read Brunson's deposition? A.—What?

Q.—You say you haven't read Holderness's deposition? A.—I haven't read Holderness's deposition.

Q.—Do you deny that it was known as the Brunson-Holderness treatment? A.—It was known as the Holderness treatment, but Holderness and Brunson were administering the treatment.

Q.—Did you have any dissolution arrangement with Holderness when you left here? A.—When I left him he paid me for the interest that he had given me; we didn't have any contract at all except oral.

Q.—You had an oral arrangement with him under which you were not to use his treatment, did you not? A.—I did.

Q.—You left here and went back then to Arkansas? A.—What is that?

Q.—You left here and went back then to Arkansas? A.—I left here and went to Arkansas, then to Chicago.

Q.—In that interval between your leaving El Paso and your return to El Paso what were you doing? A.—Practiced medicine in Arkansas, Little Rock.

Q.—What treatment did you use up there? A.—I was using my own.

Q.—How soon after you left here was it you claim you discovered your own treatment? A.—I was working on my treatment and had it perfected before using Holderness, but I never had given mine.

Q.—Did you use eucalyptus oil in your treatment? A.—What kind of oil?

Q.—Did you use eucalyptus oil? A.—I won't answer that question.

Q.—You decline to? A.—It is my own private formula, of value.

Q.—Did you use oil of pine in your treatment? A.—I refuse to answer that.

Q.—Do you use petrolatum in your treatment? A.—I won't answer it.

Q.—Do you use menthol? A.—I won't answer.

Q.—Doctor, you are asking this jury to pass upon whether your remedy had a therapeutic value or not? A.—It has a therapeutic—

Q.—Wait a moment. You are asking this jury to pass upon whether your remedy had a therapeutic value or not, are you not? A.—I don't think the jury could act on the therapeutic value; they don't know anything about medicine.

Q.—You are asking them to pass upon the genuineness of your remedy? A.—Asking them to pass on the evidence that is brought before them.

Q.—And you decline to disclose to this Court or to this jury the contents of your formula, do you? A.—I endeavored to get a scientific investigation and offered my formula, to give my formula.

Q.—Yes or no, do you decline to disclose to this Court and to this jury? A.—I do.

Q.—Of what your formula consists? A.—I do.

Q.—You did that when we took your deposition March 8th, when we took your deposition you refused when we asked you? A.—I thought that was entirely irrelevant.

Q.—You declined, didn't you? A.—Yes, sir.

Q.—And you decline at the present time? A.—I do.

Q.—And you are unwilling to submit to the defendant in this case, or to this jury, the contents of your formula? A.—Why should I do it when they say they have analyzed my formula and know what it is?

Mr. Brown:—Your Honor please, we ask that Dr. Brunson be required to state the contents of his formula. We believe it essential to the defense in this case. He is asking in this case, and one of the very vital questions to be passed upon, is whether or not his formula has therapeutic value. We deny that it has. We want to submit it to doctors and qualified chemists.

The Court:—The Court will excuse the jurors for a few minutes, and they may remain outside, and the Court will hear from counsel and pass on it as to the legal question.

The jury was thereupon excused from the court room at 3:07 p. m., and during their absence the following proceedings were had:

The Court:—The Court will hear from counsel for defendant as to the demand made by you on the Court to rule that the formula should be forthcoming, and the Court will then hear from Counsel on the other side in the case. The Court will hear from counsel for the defendant first. You may be seated, Judge Sweeney.

Judge Sweeney:—I was trying to get the motion.

The Court:—There was a motion filed to this Court reciting that on taking of the deposition of the plaintiff in this case these questions were propounded to the plaintiff at such time, asking that he reveal the contents of his formula. The Court deferred ruling upon the same, stating that that was a question that could be raised at the time of the trial, and that the Court would hear from counsel on both sides at that time. That time has arisen, and the Court will hear from you.

Mr. Brown:—I want to ask Dr. Brunson one question in connection with this.

Q.—Dr. Brunson, isn't it true that you now contend, and have always contended, that chemists could not analyze your solution or preparation? A.—They can find chemicals like carbon, hydrogen, oxygen and nitrogen, but that is as far as they can go, organic substance.

Q.—And the only way that they can find that out is from what you tell us, or what you say your formula contains? A.—They claim they have made an analysis of it.

Q.—Answer my question. Isn't it true that no analysis can determine what the contents are, and the only way we can determine is what you say it is? A.—That is my opinion, but it may not be the chemists' opinion.

Mr. Brown:—Your Honor please, that is a very vital question in this case. Dr. Fishbein's telegram, upon which they attempt to base a plea for libel, states that this solution is of no therapeutic value; we allege that the Holderness treatment was of no therapeutic value, and that they are substantially the same solutions, the same formula. The plaintiff in this case is contending to the contrary. It is one of the very elements to be determined by this Court and by this jury as to whether or not the formula has a therapeutic value. From his own lips come the words that in his opinion we cannot determine what the contents are except as to certain organic substances. It leaves the matter entirely in doubt. The matter rests within his own mind and his own cognizance as to what the contents of this formula may be. All doubt can be removed from the mind of this Court and the jury if he makes a true and correct statement as to what the contents are. We then can have testimony of experts testifying upon the therapeutic value of this solution and can then determine whether or not it has such value as he claims it has, or hasn't the value as we claim it has not. In other words, we can determine whether or not his remedy has a therapeutic value. Under the circumstances we feel that as he has invoked the jurisdiction of this Court that it is a slander of him, a libel, and a libel of his remedy, and we feel that Dr. Brunson should be required to make this statement to this Court. We have no authorities upon the subject. I don't know that the question has ever arisen before of admissibility of evidence like this in a Court. There are, of course, analogous instances where parties have from time to time been required to disclose certain information which was vital to the defense or to the issues in the case. We respectfully submit plaintiff in this case should be required to divulge this information. If honestly it has value this Court ought to know it, and if to the contrary this Court and jury ought to know. That is one of the very issues, and he can settle one of the issues at this very time possibly by disclosing it. This same question was raised, if Your Honor please, in the Brinkley case down at Del Rio when one of the doctors was on the stand testifying. We are calling the Court's attention to this matter. The Court is not bound by this ruling of that Court, but I understand Judge McMillan required them to disclose it.

The Court:—He did not have any disposition not to disclose it in that case and proceeded to tell it.

Mr. Brown:—As I read the transcript—

The Court:—What he was doing, and so forth, and did testify as to what he used at different periods of time.

Mr. Brown:—Has the Court a copy of the transcript there of what occurred at that time? I understand the witness declined at first on the ground this particular formula was private, and then the Court required him to answer it.

The Court:—The Court has not the transcript.

Mr. Brown:—The question arose while the witness Peterman was on the stand and was testifying, and he declined to answer the question because it was his secret formula, and the Court said "You will have to answer," and he answered.

The Court:—I will hear from counsel on the other side as to what authorities you have. Have you finished, Mr. Brown?

Mr. Brown:—Yes, sir, at the present time.

The Court:—The Court will be very glad now to hear from you fully on this question. It is a very important question in this case. This matter may perhaps turn upon this very question. Therefore the Court invites counsel to avail themselves of the opportunity, which the Court now gives them, to discuss this question and present to the Court all reasons and authorities they have that touch upon the question.

Mr. Quaid:—If your Honor please, I would first like to recall, before I present a few authorities, the condition of the record in this case. First we have a sworn motion of the defendant's counsel to the effect that defendant expects to show to the Court he has an analysis of this solution made, and he further expects to show by said analysis that said solution has no therapeutic value. That is the first thing I would like for the Court to bear in mind. They say they have an analysis of our medicine, and swear to it, and also swear to the fact that the solution has no therapeutic value. As far as therapeutic value is concerned I am maintaining that this idea, the fact that they say it has no therapeutic value, would lead us to believe that there is nothing that is wrong with it or injures the public health or anything like that. Some of the cases go off on the point of forcing a man, especially in a criminal case, to show his formula because it is something against public health connected with it, but the mere fact that they say it has no therapeutic value would be argumentative to say the least of it.

The Court:—Have we or not that question here? Under our statute, the Texas statute, if the matter is a matter of public concern; the question is on a question of health, and whether one is advertising it to a considerable extent, and whether that is or is not a matter of public concern, a matter of concern to the public. Then we have here the question of defense of truthfulness of the statements. Those are questions that are to be considered here. We have not arrived at a point in this case but what the Court ought to have gone further into that before definitely ruling on this question, as to whether or not he is to disclose the formula or not. This is a matter, in the opinion of the Court, of very considerable moment in this case, as to whether he should be called on to reveal his formula. He is the plaintiff, brought the suit, and the other parties meet the situation by saying they have analyzed it, and perhaps they have analyzed it, and perhaps they have not. That has not been shown; as far as he is concerned he says they can't analyze it. The question of therapeutic value is a matter within the medical realm, and perhaps we will have to get testimony on that question from medical experts. I won't interrupt you further. I want to get your views.

Mr. Quaid:—They say they have had an analysis of it; they say it has no therapeutic value. The testimony thus far in this case is that if there was a disclosure of the formula right now it would not do any good as far as knowing whether or not it was good as a tuberculosis cure, because the testimony so far is that you have to take the medicine and apply and observe its effects for sixty or ninety days, or maybe longer. I was just laying down the facts first before I come to my law. First I would say that the formula of this kind is a property right, that is valuable to the party owning it. That has been held by the Supreme Court of the United States in two different cases. I would say first it is a property right that he should not be made to give up just idly. First I would like to call the Court's attention to some expressions on page 743, Corpus Juris, volume 70, section 897: "If disclosure will depreciate its value, a witness has a qualified, but not an absolute, privilege of refusing to disclose a trade secret; he should not be compelled to disclose such a secret where to do so is not essential to the ends of justice." And a note to that section—

The Court:—Now, what are the facts in that particular case? The case is so much more illuminating.

Mr. Quaid:—I first lay down the general position. I have some cases that I will come to (reading): "The policy of the law is unquestionably that of fostering and protecting trade secrets, as is shown by the laws affecting their registration, and, unless the interests of justice imperatively demand their disclosure, a disregard of valuable property rights arising from enforced disclosure, whether by means of contempt proceedings or otherwise, approaches at least the confiscation of private property. Willson v. Superior Court of Los Angeles County.

The Court:—The question is whether he, as plaintiff in this case, or just how the question arose, it must necessarily be a question whether or not the ends of justice necessitate it.

Mr. Quaid:—I have some cases here which I expect to present. I want to lay down the general proposition of law it is property rights which the Court is slow to force disclosures, and does not do so unless it is imperatively necessary to the ends of justice.

Now, the case, and I was not able to get this case, it is an advance opinion, of B. B. X. Chemical Company v. Cataract Chemical Company, Western District of New York, decided October 24, 1938, decided by Judge Knight. In patent infringement suit in which defendant's interrogatory asking plaintiff to give analysis of defendant's composition alleged to infringe was not required to be answered where plaintiff had already specifically designated composition made and sold by defendant which it charged as infringement since defendant either knew analysis or was in position to obtain analysis.

The Court:—This plaintiff now says you can't do it.

Mr. Quaid:—I know, Your Honor, but they swear they have got it, and that is a part of the record in this case under oath.

The Court:—Both of them are in the record.

Mr. Quaid:—Now, the case in the 63rd L. R. A., page 255, Stewart v. Hook. In this case the plaintiff brought suit to enjoin defendants from using their formula.

(Mr. Quaid thereupon read from said opinion which the reporter did not take.)

The Court:—Mr. Quaid, just to illustrate the situation in which you might find yourself. The Court is not ruling on this question just at this time, perhaps, and perhaps is. It is up at this time. To illustrate, suppose the testimony comes in here to this effect, testimony introduced on trial of this case, is analyzed, can be analyzed, and that the analysis shows it is worthless, what would be your situation on the ground of the defense of truthfulness of the statement?

Mr. Quaid:—That has nothing to do with the matter. If the analysis shows it is worthless and has no therapeutic value then we have not been libeled, that is how I see the matter.

The Court:—Haven't what?

Mr. Quaid:—We have not been libeled.

The Court:—You have a man who takes the stand and testifies it is impossible to analyze, he has locked up in his bosom and withholds the material facts that will be material to show the true worth. I am going to let you go on further in the case, but this question is up in this case big and strong from now on.

Mr. Brown:—May I reply for just a moment?

The Court:—Yes, you may reply. The Court has already replied to his infringement case. It is not an infringement case where the plaintiff is bringing a suit for somebody else using a trade name or infringing on something. He has got a question in this case, and you have no case you have presented. Therefore we must do the best we can, no case in which perhaps the plaintiff himself—I will put the matter—by bringing a suit—he did not have to bring the suit.

Mr. Quaid:—Your Honor—

The Court:—That is all. I merely make that suggestion. I will hear from you further, any authorities any of you have or can find, within reason, to present the Court, and the Court will probably rule on that.

Mr. Brown:—We can fortify ourselves by replying to counsel in just a few moments time.

The Court:—That is your privilege.

Mr. Brown:—In the first place, the case of *Stewart v. Hook*, which counsel recites to be found in 63 L. R. A., the case of the Georgia Supreme Court, is not in point, for this reason: In that case a party was seeking to restrain a party who had worked for him as an employee, and as result of that confidential relation obtained knowledge of his secret formula and was about to disclose it to the world, and the Court said it was a proprietary right, a property right which he was trying to keep, and keep them from divulging out to the world abroad. In our motion asking that plaintiff be required to disclose his formula, which was filed on the 8th of May, we state the defendant is informed that plaintiff will contend it is impossible for a chemist properly to make an analysis of said solution and that for that reason this defendant says it is important that he obtain information from the plaintiff as to the contents of said solution in order that he may submit same to a reputable medical man or practitioner and obtain their opinion, and so forth. We are confronted with that very condition upon the stand here now when the plaintiff says in his opinion and judgment it cannot be obtained accurately—

The Court:—The Court announces at this time that the Court reserves ruling on that matter and will rule on it later in the progress of the case.

Q.—Doctor, I believe I understood you to say that immediately, or shortly, after you dissociated yourself from Holderness, in 1921 or '22, you discovered your own treatment? A.—I had it before I joined with Holderness but I never had used it.

Q.—You had discovered it, then, before you had joined with Holderness? A.—Yes, but I never had used it.

Q.—You preferred to use his? A.—He said his treatment had been used a good many years by his father.

Q.—You hadn't used your treatment up to that time? A.—I hadn't tried mine out.

Q.—I believe you said nature is the only doctor? A.—What is that?

Q.—In tuberculosis cases, I believe you said nature is the only doctor? A.—No, I said aiding nature is the only doctor.

Q.—You claim to have the only effective treatment of tuberculosis, do you not? A.—I claim what?

Q.—You claim to have the only effective treatment for tuberculosis, is that not true? A.—Yes.

Q.—For how long a time have you been claiming that you had the only effective treatment for tuberculosis? A.—That I have been saying so?

Q.—Yes. A.—I haven't said so.

Q.—Didn't you just now say so? A.—I did say so just now, but I haven't made that public, I don't claim that it is a specific.

Q.—Are you claiming now for the first time that it is the only effective treatment? A.—I mean by that drug treatment.

Q.—I don't understand you. A.—Giving drugs.

Q.—I am asking you about your treatment, do you say now your treatment is the only effective treatment? A.—The only one I know of.

Q.—In all your experience, you have never come across another treatment you know of as effective, is that true? A.—Not as effective as mine.

Q.—You are certain about that? A.—I know it.

Q.—In your mind, that is a positive, demonstrated fact, is it? A.—That my treatment is?

Q.—Is the only effective treatment? A.—That I know of.

Q.—Well, were your treatment and Holderness's treatment the same? A.—I never knew Holderness's formula at all.

Q.—What is the essential difference between the two? A.—I don't know. He never has seen my treatment at all, and I never did know his formula.

Q.—Then you administered Holderness's treatment without knowing what it was? A.—Yes.

Q.—And you also recommended his treatment to others without knowing what it was? A.—Yes, because I got results.

Q.—And you have maintained in this case that a person couldn't tell whether or not a treatment was effective without knowing of what it consisted, isn't that true? A.—Without knowing what it consisted of?

Q.—Yes. A.—Absolutely, you can tell.

Q.—Haven't you maintained you couldn't tell whether or not the treatment had any value without knowing of what it consisted? A.—Not unless you tried it.

Q.—Over how long a period of time? A.—It depends on the class of patient you have, anywhere from two months to five or six months.

Q.—But you finally discarded Holderness's treatment? A.—What is that?

Q.—You finally discarded Holderness's treatment, I say, you finally discarded the treatment of Holderness? A.—I don't understand what you say.

Q.—Let me put it in simpler English. You finally quit using Holderness's treatment? A.—Yes, I finally quit using Holderness's treatment.

Q.—And agreed at that time you wouldn't use it any more after you sold out? A.—And I never have!

Q.—And you can't tell us in what essential particulars that treatment differed from your treatment? A.—It was given the same way, but, not knowing the contents of his formula, I couldn't say.

Q.—Are they given identically the same way in each instance? A.—They are given the same way, by inhalation.

Q.—Describe to us now the way in which the treatment is administered. A.—You mean my treatment?

Q.—You say they are the same. A.—Well, they use a tank of oxygen to force the medicine out of the atomizer, which breaks it up into fine globules, it looks like mist; you inhale it down into the lungs and exhale it, it is very simple and easy to do.

Q.—Is that all there is to it? A.—That is all there is to it in giving it.

Q.—What effect do you claim that this solution, which you use as a vapor, has upon the lungs? A.—It acts as an antiseptic, it liquefies the tough secretion in the lung, making it easier to expel.

Q.—What is the antiseptic element in it? A.—What?

Q.—What is the antiseptic element in it, what is it that renders it antiseptic? A.—Well, that is one thing I am not going to tell you about.

Q.—You refuse to tell that. Just how does this machine work, Doctor? A.—What is that?

Q.—Just how does this machine work? A.—There isn't any machine to it, nothing in the world but a tank of oxygen with a regulator.

Q.—What is the regulator? A.—Where you can regulate the number of pounds of oxygen you wish to use to force it out of the bottle.

Q.—Is it forced into the lungs? A.—No, it is not forced into the lungs, it is breathed, just like breathing air.

Q.—It is forced out of this bottle or container into the nostrils or mouth, and then inhaled? A.—Yes, it is an inhalation treatment; anybody that has ever used an atomizer knows just how it works.

Q.—It is as simple as that? A.—Sure, it is simple.

Q.—Doctor, how do you go about diagnosing a case of tuberculosis? A.—Just like other doctors do.

Q.—Well, just tell us how? A.—Well, I use a stethoscope and use palpation and auscultation.

Q.—What does palpation consist of? A.—Palpation consists of palpating the lungs to see where there is dulness.

Q.—How do you do that? A.—You put your hands, you can feel when breathing if there is an affected lung, that is what is called palpation, putting your hand on it.

Q.—What is the next process? A.—Auscultation is the best way to determine.

Q.—What is that? A.—I use a stethoscope.

Q.—What do you mean by auscultation? A.—Listening at the air going through the lung.

Q.—Is it necessary to have good hearing for that purpose? A.—Well, you can hear pretty good when you have got it in your ear, just like using a telephone; I have known many deaf people that could hear over a telephone when they couldn't hear a conversation.

Q.—It is necessary to have good hearing to hear particular rales? A.—You hear crepitation, subcrepitation, moist rales, sibilant rales, all kinds of rales.

Q.—It is essential you hear to determine whether the lungs are working? A.—Do you want to know what causes those rales?

Q.—I don't care, I want to know about the process. A.—As a usual thing, you get the personal history when they come in; they know they have tuberculosis before they come, because the majority of patients that come down here have advanced tuberculosis.

Q.—They don't come to you to find whether they have it? A.—They usually know before they come, but I examine them to find out just what I think about it.

Q.—Did you examine them in '21 and '22 to find out what you thought about it? A.—What?

Q.—Did you examine them in '21 and '22 to find out what you thought about it? A.—No, we had a doctor doing the examining.

Q.—You didn't do any examining at that time? A.—No.

Q.—You just collected the fees, is that correct? A.—Yes, I didn't have a license to practice in Texas, consequently I didn't break the law.

Q.—And you were using upon them a formula which you didn't know the contents of? A.—I used one I didn't know the contents of?

Q.—At that time you used a formula which you didn't know the contents of? A.—Yes, and giving treatments and getting results is the only way you can tell the beneficial effects of a formula.

Q.—What else do you use in connection with your diagnosis? A.—Well, sometimes I have the sputum examined and x-ray pictures made.

Q.—Anything else? A.—No, that is about all that is necessary.

Q.—Have you been personally using those methods in your diagnosis? A.—The methods I have just spoken of?

Q.—Yes. A.—Many times I don't have an x-ray picture, because tuberculosis is a poor man's disease and \$10 is worth a lot to them; when I know I have made a correct diagnosis by physical examination, I don't put them to that expense.

Q.—You claim to have made a life study of tuberculosis? A.—What?

Q.—You claim to have made a life study of tuberculosis? A.—No, I haven't made a life study.

Q.—How long have you been specializing in it? A.—Since about the 1st of October 1920.

Q.—What have you studied, what authors? A.—I haven't found any authors that agree with my theory of tuberculosis.

Q.—Then you don't rely upon any authors? A.—No, sir, I study my patients from bedside and office.

Q.—Have you been studying any standard works on that subject? A.—Yes, I have read a good deal, but I don't agree with them.

Q.—What books? A.—Potter! Can any one say he is not good?

Q.—I am asking you, sir. What authors—Potter? A.—Potter.

Q.—What other author? A.—Well, I have read—I don't know that I can mention them right now, in the practice of medicine, Tyson, Anders.

Q.—I am asking you about books on the subject of tuberculosis, consumption. A.—The practice of medicine certainly has that in it.

Q.—A lot of other subjects, too. I am not asking you about other subjects, but what special works you have studied on tuberculosis? A.—I have studied more tuberculosis from watching my patients.

Q.—Name the authors. A.—I told you Potter.

Q.—That is the only one you can name at the present time? A.—Right now. I can name several in the morning.

Q.—Do you have to go look them up to tell me? A.—No, I have the books right there.

Q.—You have to refresh your memory? A.—To get the names of the books.

Q.—Well, have you attended any other than the clinic in Chicago about '22 or '23, have you ever attended any tuberculosis clinic, if so, what? A.—In Chicago.

Q.—Have you attended any tuberculosis clinic anywhere since '22? A.—No, I don't think it necessary, because they don't know anything about tuberculosis.

Q.—You are resting upon your own assurance that in these tuberculosis clinics they don't know anything about tuberculosis, and you haven't gone and attended? A.—If they knew much about it, why haven't they found a cure?

Q.—You haven't seen fit to rely on them or go to them? A.—No, I don't care to go and see what somebody else said that didn't know anything about it.

Q.—You have testified under oath that these specialists at these clinics didn't know anything about it? A.—What is that?

Q.—You have testified under oath that these specialists at these clinics didn't know anything about the subject; is that correct? A.—I never heard of them knowing very much about it, they aren't curing any one.

Q.—You are about the only one in this part of the country that does cure them? A.—A certain percentage of people will get well without any treatment, no matter where they might go.

Q.—You have claimed upon many occasions you are about the only one in this part of the country that knows anything about it? A.—I never made that claim at all.

Q.—You have never claimed to have an international fame along that line? A.—Oh, no. It has been more defame than fame.

Q.—You don't belong to the local medical society, do you? A.—Never applied.

Q.—You don't belong to the state medical association? A.—I couldn't unless I belonged to the county.

Q.—You don't belong to the American Medical Association? A.—No, thank God, I never will.

Q.—Have you ever belonged? A.—I have.

Q.—Have you belonged either to the local or state medical associations? A.—Not in Texas.

Q.—Did you in Arkansas? A.—Yes, up to the time I resigned from the county medical society and automatically I was out of the state and A. M. A.

Q.—You tried to get back in that society, isn't that true?

A.—No, it is not true, and they can't show I ever made application to join.

Q.—Have you ever attended any medical conventions in the last fifteen years? A.—No, not last fifteen years.

Q.—Have you in the last twenty? A.—No, I haven't belonged to a medical society and I didn't care to push myself in.

Q.—You don't believe in tuberculosis clinics and medical conventions, do you? A.—I believe in medical conventions in certain things.

Q.—You don't believe in tuberculosis clinics? A.—No.

Q.—Do you belong to any special tuberculosis societies? A.—No, I don't belong to any medical societies.

Q.—Have you ever belonged to any special tuberculosis societies? A.—No, because I wasn't treating tuberculosis at the time I resigned from the medical societies.

Q.—Have you ever affiliated yourself with men treating tuberculosis? A.—No, never had any occasion to.

Q.—Do you believe that the United States Public Health Service knows anything about tuberculosis? A.—They all know how to make a diagnosis and tell you how long you are going to live and put you to bed and let you stay there.

Q.—Until you die? A.—A few get well.

Q.—Does the Veterans' Bureau know anything about tuberculosis? A.—They know more about getting the money than anything else.

Q.—That is your idea of that? A.—Yes.

Q.—They know more about getting the money than about treating and dealing with tuberculosis? A.—Repeat that.

Q.—I say, they know more about getting the money from whom? A.—From the people generally. You never hear from the National Tuberculosis Society until the latter part of November or December, and the papers publish what they are doing to exterminate the white plague.

Q.—My question was the Veterans' Bureau; do they know anything about tuberculosis? A.—I don't think they do.

Q.—How long have you had that idea? A.—I have had it a pretty good long time.

Q.—It is your idea you are the only physician in El Paso that knows anything about the treatment of tuberculosis or correct way of handling it? A.—I didn't say that; I do say I am the only one giving drugs and getting results from the treatment.

Q.—Are you a member of the American National Red Cross? A.—No.

Q.—You don't believe in it? A.—I donate to them nearly every year.

Q.—You don't believe in it? A.—Oh, yes, I believe they do a good deal.

Q.—Do you believe in the work of the Red Cross in connection with tuberculosis? A.—Repeat that.

Q.—Do you believe in the work of the Red Cross in dealing with the tuberculosis situation? A.—That is not clear.

Q.—Why is it you can hear your own counsel and can't hear me?

Judge Sweeney:—Because I speak plainer.

The Court:—Don't argue with the witness.

Q.—You can hear your own counsel? A.—If you step up here I don't have to ask you to repeat.

Q.—I don't want my back to the jury. You can hear your own counsel? A.—Do what?

Q.—You can hear your own counsel? A.—I can hear Judge Sweeney but not Mr. Quaid.

Q.—And you insist upon my repeating the questions repeatedly to you? A.—What?

Q.—You insist upon my repeating the questions to you? A.—If I can't hear them, why should I answer something I don't understand?

Q.—You told us that you are very much pained and grieved by this telegram which DeWitt Wallace sent in January of 1938, is that correct? A.—That is correct.

Q.—Had you seen the Hruby report of 1921? A.—I didn't see Hruby's report until I read it in your answer to our petition.

Q.—You didn't see it when it was published in the Chicago Examiner in '21 or '22? A.—There was something published in the Chicago paper prior to that time and I wanted to answer it, and Holderness wasn't willing for me to do it; the next thing I saw, if you want me to tell you?

Q.—Go ahead. A.—Was in Hygia, it stated two quacks—

Q.—Don't make a statement about what Hygia stated. This telegram of January 1938 wasn't the first time your feelings had been hurt, is that correct? A.—That brought it right home, when it stated I was administering a dangerous fake.

Q.—You came in this court in 1921 and filed a suit for libel against Hendricks-Laws, claiming your feelings had been hurt? A.—Yes, and I went after them, too.

Q.—That suit was finally dismissed? A.—It was dismissed from the mere fact that I didn't have the money to come down here and fight it out.

Q.—You came into this Court in 1921 and filed a suit for libel against Hendricks and Laws, claiming your feelings had been hurt, did you not? A.—Yes, and I went after them, too.

Q.—It was dismissed? A.—It was dismissed only because I didn't have the money to fight it.

Q.—In that suit you claimed the same hurt feelings you are at the present time, didn't you? A.—Yes.

Q.—And that was eighteen years ago, in 1921? A.—That was in 1921.

Q.—But you didn't have money enough to fight it but you did have money enough to pay a doctor \$250 a week to work for you? A.—Yes, we were making money then, until we got libeled.

Q.—Are you acquainted with DeWitt Wallace? A.—With Dewitt Wallace?

Q.—Yes. A.—No.

Q.—How long you—how long have you known of DeWitt Wallace? A.—I have been reading the *Reader's Digest* for quite a long while.

Q.—You never have met him and are not personally acquainted with him? A.—No.

Q.—Do you know anybody in Pleasantville, New York? A.—Not a soul.

Q.—You do not now and never have known any one there? A.—To the best of my knowledge and belief I do not.

Q.—You did know Mary Rose Bradford? A.—I met her here.

Q.—How did you happen to come in contact with her? A.—She asked me for an appointment and I went to see her.

Q.—At whose instance? A.—Miss Joteen Sweeney.

Q.—Judge Sweeney's daughter? A.—Yes.

Q.—At her instance an appointment was made with you for Mary Rose Bradford? A.—She did.

Q.—What was the purpose of that meeting? A.—I did not know what the purpose was. I met her. She asked me a great many questions about tuberculosis, about treatment and that was about all there was to it until I received the telegram that she got from DeWitt Wallace.

Q.—I believe you claim you did not know the purpose of her interviewing you? A.—I did not know when I went to see her.

Q.—You did not have any idea what that purpose was until you saw that telegram that DeWitt Wallace sent to her? A.—That was the first I knew she was going to attempt to write a story.

Q.—Was that telegram delivered to you by Mrs. Bradford or Miss Joteen Sweeney? A.—I don't remember who it was, but it was delivered.

Q.—Do you know about when it was delivered? A.—About the 25th, I think, of January '38.

Q.—That was about the day it was sent. Is that correct? A.—Yes.

Q.—You can't tell me who delivered it? A.—I do not remember who delivered it.

Q.—Where was it delivered? A.—I don't remember that. If I did I could tell you who delivered it.

Q.—Can you tell me the time of day, morning or afternoon? A.—No, I cannot.

Q.—You never did see Mrs. Bradford after that did you? A.—I never saw her again.

Q.—Did you know her before that? A.—No, I did not.

Q.—Did you know who she was at that time? A.—I knew that Bradford was a writer, was writing a book.

Q.—That is her husband, Roark Bradford? A.—Yes.

Q.—You did not know what her business was? A.—No, I did not. I just thought she was a housewife.

Q.—Dr. Brunson, you somewhere published a purported testimonial from a man named Frank Ehret of Roswell, New Mexico. Is that correct? A.—That is correct but he is not in Roswell, New Mexico.

Q.—Do you know where he is? A.—He is in Albuquerque.

Q.—Did you ever write to him? A.—I have written to him a good many times.

Q.—Do you recall at one time being placed under oath and testifying to a letter which you wrote to Frank Ehret? A.—What is it you want to know about it?

Q.—Do you remember having been placed under oath in the district attorney's office here some years ago and having testified with reference to a letter you sent to Frank Ehret? A.—Yes, with a check in it.

Q.—With a check of \$20? A.—Yes.

Q.—You identified that letter at that time? A.—I did.

Q.—You identified a copy of it didn't you? (handing letter to witness) A.—The \$20 check was my check I sent him.

Q.—You sent him that letter? A.—That is a copy of the letter.

Q.—And you so admitted under oath before the district attorney at the time? A.—Yes. I do not think that was breaking any law, and the Grand Jury didn't think so.

Mr. Brown:—We offer this letter in evidence, Your Honor.

The Court:—There being no objection, it will be admitted.

The letter was then received in evidence, marked Exhibit D-1, was read to the Jury and is in words and figures as follows:

(COPY)

ASA BRUNSON, M.D.
PRACTICE LIMITED TO TUBERCULOSIS
717-21 CAPLES BUILDING
EL PASO, TEXAS

July 18, 1929

Mr. Frank Ehret,
500 N. Richardson
Roswell, New Mexico.

I herewith enclose my check for twenty dollars, your commission on Miss Moore. You would have had this money before now, but we have written to you and our letters were returned, therefore, I did not know how to reach you and I wrote Mrs. Moore for your address. I received your letter, and now know how to reach you.

I certainly do appreciate your efforts in my behalf and assure you that every patient that you get for me, you will receive twenty dollars by return mail.

If it is convenient, I would like for you to see Miss Moore occasionally to see just how she is getting along.

It is hot as the devil here and very little news.

Trusting to hear from you soon, I am

Yours very truly,
Asa Brunson
ASA BRUNSON, M.D.

AB-AH

P.S. We have printed a booklet and have put in a list of cured patients and their addresses, so that you may write to them. Your name is among them, so I will appreciate your answering any inquiries. I am enclosing a booklet.

The Court:—What was the date of that?

Mr. Brown:—July 18th, 1929.

Q.—You believe it is entirely in keeping with medical ethics for a physician to have a secret formula which he advertises or has advertised and to use it in the treatment of patients, do you? A.—I am anxious to make the formula public to the world but not until I get a scientific investigation.

Q.—You heard the letter, you could get an investigation if you desired? A.—Do you suppose I want to send it to the enemy's camp? It would be condemned no matter what it was.

D-1

Q.—You condemn all the members of the American Medical Association as your enemies and in the enemy camp? A.—The ones in the office of the American Medical Association and as evidence they are they never answered a letter I wrote.

Q.—You have consistently declined to turn anything over to the Council on Pharmacy and Chemistry of the American Medical Association or that bureau, you have absolutely consistently refused to turn anything over to that Council? A.—Because I know they could not tell anything about it.

Q.—Answer my question. You have always refused? A.—They never asked for it.

Q.—You hear Dr. Fishbein's letter, you could get the investigation if you wanted it? A.—That was Mr. Ben Altheimer.

Q.—You have refused at any time to turn it over to the Association? A.—I couldn't get a reply from them.

Q.—Just answer my question, and you refuse to do it now? A.—I certainly wouldn't give it to the enemy now. That is against the Bible.

Q.—How do you make sputum tests? A.—I do not make them. I pay for having them made.

Q.—Whom do you have to make them? A.—I have Dr. George Turner make them, Waite to make them.

Q.—Who else? A.—Dr. Hummell.

Q.—In the past year how many sputum tests have you had made and by whom? A.—I couldn't answer that question, I don't remember.

Q.—As a matter of fact have you had any? A.—I don't know. I haven't been treating patients who can pay for any. They can't pay the \$2—

Q.—Can you tell me of any sputum tests you have had made in the last two years, and if so, sputum of whom and what doctor made the tests? A.—I can't remember that. I suppose Dr. Turner could look at his files and tell how many I had made.

Q.—Do you know of a single one? A.—Yes.

Q.—What one? A.—I know of several.

Q.—Name them. A.—I know Mr. Robert Hamilton of Chillicothe, Texas. I had his sputum examined—

Q.—By whom?

Mr. Sweeney:—If Your Honor please, he does not permit him to answer the questions.

The Court:—Permit him to answer before another question is asked. The Court still does not have the name.

Mr. Brown:—A Mr. Hamilton from Chillicothe, Texas.

A.—It was sometime two or three years ago. I would have to look at my own records to see.

Q.—You cannot name me more than one person whose sputum you had tested in the last year, offhand? A.—Does that have anything to do with this case?

The Court:—Mr. Witness, you will not ask questions of counsel or argue with counsel.

The Witness:—I beg your pardon.

Q.—This man Hamilton of Chillicothe, Texas, is the only one whose name you can remember in the past two years? A.—I do not try to remember that. You make a sputum test and forget it.

Q.—You have not had so many patients you cannot remember? A.—I have not had many patients in the last two or three years.

Q.—You have not had many in the past three or four years? A.—No, it has been drying up since 1930.

Q.—Since 1930 your practice has been drying up? A.—Been getting less and less each year.

Q.—That was before the DeWitt Wallace telegram was sent? A.—After the *Hygeia* article came out.

Q.—I am talking about the DeWitt Wallace telegram. A.—It just began drying up that much more, shrinking up that much more.

Q.—There was not much to shrink since 1938 in January was there? A.—Since when?

Q.—January 1938. A.—I told you in the deposition what I made last year \$1,790.

Q.—It was approximately the same amount the previous year? A.—The previous year was a little more than that. That was '37. I think it was about \$2,400 or \$2,500.

Q.—That was gross you testified in your deposition? A.—Gross?

Q.—Yes. A.—Absolutely.

Q.—And in 1938 a little less than \$1,800? A.—Yes.

Q.—Did you ever submit your tests to any board of Army Doctors? A.—I never did, no.

Q.—Do you recall anything with reference to an offer of 100 patients to be treated by them and a hundred patients to be treated generally? A.—I wrote them and made them that proposition and they wrote to the army and I wrote to the army and they did not answer my questions.

Q.—Do you recall whether the United States Surgeon General did make an investigation and you did turn over eleven patients for that purpose? A.—That was Holderness.

Q.—Did the Surgeon turn over eleven to you to be treated? A.—No, they never sent any to me to be treated.

Q.—Did the Army ever try your treatment? A.—No, they never did.

Q.—They never did have any patients from William Beaumont take the treatment? A.—They never did.

Q.—You are certain about that? A.—I know it.

Q.—How about the Holderness treatment? A.—The Holderness treatment—they were ordered by the Secretary of War and I think they wrote to the colonel in charge at William Beaumont and he sent three officers and they informed us they were going to investigate the treatment. I said that that was what we wanted. They came up, examined two or three patients each morning for three mornings. Then they told me it was very hard for them to come to town and they would send a conveyance to get the patients and we could send out four or five every day and they would send them back. They didn't have the road paved to William Beaumont for about ten or twelve blocks and it was very rough and the patients were treated rough in making the examination and after the third day, which made six days altogether, the patients would refuse to go out there. Now they were our patients, private patients, paying for treatment and we could not make them go out there and Major Scott—I believe he is a colonel now—the ranking officer—

Q.—Let us not go further with that. The upshot of it was the matter was dropped? A.—Yes.

Q.—And the Medical Department never did take up the Holderness or the Brunson treatment? A.—They did not take up mine and did not make much investigation of the Holderness treatment.

Q.—They discarded all transactions with the Holderness treatment from that time? A.—Yes.

Q.—You do not know what report they made on it yourself, do you? A.—No, I never did.

Q.—Prior to January 1938 had you ever met Dr. Fishbein? A.—Never had.

Q.—You would not have known him if you had seen him? A.—I think I would on account of his picture which I have seen.

Q.—But you had never met him? A.—Not personally.

Q.—When did you first meet him or see him personally? A.—The first time I saw him personally was this morning.

Q.—In this Court room? A.—Yes.

Q.—And you never had personal contact with him? A.—Never had any personal contact at all.

Q.—You do know that he is an editor of the American Medical Association JOURNAL and has been for a good many years? A.—He has been since Dr. Simmons was retired in 1924.

Q.—And he has been a number of years editor of *Hygeia*? A.—He has been since 1924. He was assistant to Dr. Simmons from '13 until he took Dr. Simmons's job.

Q.—You do not know what, if any, connection he has with *Reader's Digest* now? A.—No, I do not.

Q.—Doctor, when did you say that you first met Dr. Hruby? A.—Dr. Hruby?

Q.—Yes, sir. A.—It was in the summer of '21; I don't know whether it was the latter part of July or the first part of August.

Q.—Up to that time were you personally acquainted with him? A.—No, I never heard of him until he came into the office.

Q.—You did find out who he was? A.—Yes, very much so.

Q.—Do you know what his occupation was in Chicago or what connections he had in Chicago? A.—Well, he just informed me that when he came down he was a doctor sent down to investigate the Holderness treatment.

Q.—Sent by whom? A.—I don't remember his saying who sent him.

Q.—Did he tell you what institution he was connected with? A.—No. He was quite a young man at that time; I just thought he was an intern for one of those hospitals.

Q.—Did you know that he was the head of the Chicago Municipal Tuberculosis Sanitarium? A.—I didn't know at that time, and he didn't tell me.

Q.—You found out afterwards, didn't you? A.—I found out afterwards.

Q.—Do you know how long he had been connected with that institution? A.—No, I do not.

Q.—He still is connected with it, is he not? A.—Not that I know of.

Q.—Do you know how long prior to 1921 that he had been connected with that institution? A.—Are you asking me how long he had been?

Q.—Do you know? A.—I really don't know.

Q.—What time of day was it you first saw him, do you recall? A.—It was in the morning, I think about 9:30.

Q.—Whereabouts? A.—In the office of Holderness & Brunson.

Q.—In— A.—In the El Paso National Bank Building.

Q.—Now, whom did he see? A.—What?

Q.—Whom did he see? A.—Who did he see?

Q.—Yes, whom did he see? A.—Oh, he met everybody that was up there.

Q.—Whom did he interview, talk to and examine? A.—He interviewed me and also interviewed Holderness.

Q.—And who else? A.—Well, from a medical standpoint he didn't interview any one else. I think possibly he talked to—I don't know whether it was Dr. Thomas, I believe, and we just introduced him to the others that were working there.

Q.—Did he see Griffin, a man named Griffin, who had been a reporter of the *Times*? A.—Who was that?

Q.—Did he see a man named Griffin, who had been a reporter for the *Times*? A.—Did I know him?

Q.—I say did he see him? A.—He said he saw him. He didn't bring him. He stated in his report that Griffin brought him up and introduced him to me, but he didn't do it. He came up by himself.

Q.—Griffin was a patient of yours? A.—Griffin was a patient of mine, yes.

Q.—Did you take Dr. Hruby around to see any of your patients? A.—I took him to see a Mr. Martin, is the only one I remember now.

Q.—Where is Griffin now? A.—He is dead.

Q.—Do you know when he died? A.—He died in Mexico City, and I never did know just what the cause was.

Q.—Mr. Martin, who was he? A.—He was a patient. We treated him out at his home for quite a while, well, I think about two months, before he was able to come to the office.

Q.—Dr. Hruby talked to him? A.—Dr. Hruby went out with me and talked to him just a short time.

Q.—He made an examination of him? A.—No, he didn't make an examination of him.

Q.—Are you positive about that? A.—I know he did not. Martin was a very peculiar fellow; he wouldn't let him examine him.

Q.—You examined him? A.—I never examined him.

Q.—You never examined him, but you treated him? A.—A doctor that was working for us was doing the treating. I drove Dr. Hruby out there because I knew where he lived.

Q.—You said he was your patient? A.—Certainly, he was under our treatment.

Q.—But you never did examine him? A.—No.

Q.—Did you go with Dr. Hruby to see a man named McLean, who was a reporter? A.—No, Hruby called on McLean himself. He was working for the *Times* at the time Griffin was there. They were both working for the *Times*.

Q.—You don't know what transpired while Dr. Hruby was with McLean? A.—No.

Q.—Do you know a man by the name of Mr. McCloud? A.—McCloud?

Q.—Yes, a patient of yours, was he not? A.—Yes, it seems to me that I treated a Mrs. McCloud.

Q.—Did you take Dr. Hruby to see either a man or woman by the name of McCloud? A.—I don't remember if I did.

Q.—How many people did you take him to see? A.—I don't remember how many people I took him to see, but when he was examining patients in my office—

Q.—Who was examining them? A.—Hruby.

Q.—How many did he examine there? A.—Well, I don't know just how many. There was one he examined—I didn't think very much of his ability for his examinations, and I got our bookkeeper to go in there, that was a strong healthy fellow, and Hruby found he had tuberculosis in the apex of both lungs, and he was never sick a day in his life. R. E. McGaughy was his name, if you want to know his name. He was our bookkeeper.

Q.—Where is he? A.—Pine Bluff, Arkansas.

Q.—Where is Martin? A.—He has gone to his great reward.

Q.—What about McLean? A.—McLean is dead.

Q.—Griffin is dead? A.—Griffin died in Mexico City.

Q.—Is McCloud dead? A.—I don't know whether McCloud is dead or not. I haven't heard from the McClouds in sixteen or seventeen years.

Q.—But these people were all your patients? A.—They were patients. We were furnishing medicine and had a doctor employed who was prescribing it.

Q.—Whose treatments, your's or Holderness's? A.—Dr. Holderness's treatment.

Q.—At that time you had quite a few patients staying at Hendricks-Laws Sanitarium, did you not? A.—No.

Q.—Do you know whether Dr. Hruby went out to Hendricks-Laws? A.—I suppose he went all around.

Q.—Do you know whether at that time there were people in Hendricks-Laws whom you had treated previously? A.—I don't remember. I don't know whether there were or not.

Q.—You don't know whether Dr. Hruby visited them there? A.—I don't know whether he even went to Hendricks & Laws.

Q.—You don't know whether he interviewed any patients out there who had been your patients? A.—No, I do not.

Q.—Dr. Brunson, where did you have your office in Pine Bluff, Arkansas? A.—I had my office in several places.

Q.—Name them. A.—Reinberger & Collier, Sewell & Ancrum, and the Citizens Bank Building, an office over the Citizens Bank Building.

Q.—How long did you have an office over the Reinberger & Collier Drug Store? A.—I don't know that I could tell you exactly how long I was there. I think though about a year.

Q.—You had a special arrangement with them under which you were to get rent free in consideration of your prescriptions going to that drug store? A.—That was a rule among the doctors where they had offices over a drug store, they didn't charge them any rent.

Q.—And that drug store put out a number of remedies or prescriptions under the name of Dr. Brunson's Remedies, did it not? A.—Reinberger & Collier did?

Q.—Yes. A.—I found that out after Mr. McCoy went down there.

Q.—During that period of time your offices were over their drug store didn't they put out prescriptions under your name?

A.—They only put out one prescription when I was over their drug store under my name.

Q.—What was that? A.—Brunson's Famous Prescription.

Q.—Was that the prescription in which a card was given by you, or by them, in consideration of the patient buying the remedy you would give them a free treatment? A.—No, I don't remember that.

Q.—Didn't you testify with reference to a free examination, didn't you testify to that in your deposition? A.—I don't think I did.

Q.—Do you recall this question when your deposition was taken on March 8th of this year: Q.—"It was a fact they did call it 'Brunson's Famous Prescription'?" A.—"They did call it 'Brunson's Famous Prescription.'" Q.—"I will ask you, Doctor, if, in this same proceeding, that is, the case whose title I have given, you were asked this question by Mr. Danaher, your attorney, on direct examination, and if you gave this answer": Q.—"Doctor, I show you a card, which reads as follows: 'This card certifies that the bearer has purchased one bottle of Dr. Brunson's Famous Prescription and is entitled to one free consultation with Dr. Brunson. Office Fourth and Main, over Reinberger & Collier's Drug Store.' Did you ever see one of these cards before?" A.—"Yes, sir." Do you recall whether you so testified in that case? A.—That has been twenty-three or four years ago, and I just can't remember everything that happened at that time.

Q.—You won't deny under oath that you did so testify, will you? A.—If I answered it it was true.

Q.—But you do not deny that you answered it that way? A.—I won't deny it, no.

Q.—You did have some cards of that character? A.—I never had any cards myself at all.

Q.—You did honor cards of that character issued by Reinberger & Collier? A.—I understand since this case came up that Reinberger & Collier got out some cards, and I told you when my depositions were taken I did not remember much about it, it had been so long ago.

Q.—But you do not remember whether you had that sort of arrangement with them? A.—I never had any such arrangement. I think they got that out themselves and told me, and asked me if I wouldn't give them an examination.

Q.—If you did give an examination of that sort wouldn't you remember it? A.—I don't know I ever made an examination of any one that had a card.

Q.—But you don't deny it? A.—I don't remember it.

Tuesday, May 30, 1939

Dr. Brunson took the stand.

Q.—Dr. Brunson, do you know of any one in El Paso who knew of the contents of any of these telegrams that are involved in this suit prior to the time that the suit was filed? A.—Do I know whether any one else knew?

Q.—Yes. A.—I don't.

Q.—And you can't name a single person who knew of the contents of this telegram before the suit was filed other than yourself and Rose Marie Bradford—Rose Mary Bradford? A.—My attorneys, but I didn't know any one else that saw it.

Q.—The basis of your preparation or solution is some oil, it is an oily substance? A.—I refuse to answer that question.

Q.—Didn't you admit in your deposition that it was an oily solution? A.—Well, it is an oily solution.

Q.—Will you tell us whether the basis is a mineral oil, animal oil or vegetable oil? A.—Mineral oil.

Q.—And you decline to go any further, then? A.—Yes.

Q.—What were the educational requirements of this college in Memphis? A.—I will have to ask you to repeat that question.

Q.—What were the educational requirements of this college in Memphis? A.—The same as any other first class medical college.

Q.—Didn't you testify in your deposition, on March 8 of this year, that there were no educational requirements and that you weren't required to take any examination of any nature prior to entering that school? A.—That is right.

Q.—That is a fact. And you didn't at that time have a diploma from any school, did you? A.—Didn't have what?

Q.—At that time that you entered that college in Memphis, you did not have any diploma from any school? A.—No, I didn't.

Q.—You did not. There were no examinations required of any one to enter that school, were there? A.—Yes, a great many had to stand examinations.

Q.—But you didn't take any? A.—I didn't because I told them where I had been to school.

Q.—And at the time you got your license in Arkansas, you weren't required to take any examination, were you? A.—I put my diploma on record.

Q.—From that school? A.—From that school.

Q.—And that is all you were required to do? A.—That is all the Board of Medical Examiners required.

Q.—And you got a county license, was it? A.—A county license.

Q.—Did you ever take a medical examination for a license to practice medicine? A.—No, I didn't have to.

Q.—How many treatments do you give daily in administering your treatment? A.—Twice daily.

Q.—How long does each one of those treatments take? A.—The time for them to take ten inhalations.

Q.—They just take ten whiffs of that vapor? A.—Yes, sir.

Q.—And then leave your office? A.—Yes.

Q.—You require them to come to your office? A.—Twice a day if they are able to come.

Q.—Do you regard that as being consistent with the rest cure? A.—It is consistent. As far as the rest cure is concerned, they don't require rest when a patient is not running a temperature.

Q.—Well, do you only treat those who are not running temperature? A.—No, the temperature subsides in a week or ten days after I begin treating them.

Q.—But you require them, during that period of time, to come to your office twice a day? A.—Until I determine their temperature is going to continue, then I put them to bed.

Q.—How do you determine whether that treatment is going to continue or temperature is going to continue, how do you determine that fact? A.—By taking their temperature with a thermometer.

Q.—Then you put them to bed. Do you treat them in bed? A.—Until their temperature is broken.

Q.—Isn't it a fact, you administer your treatment only in your office? A.—No, I give it in the home.

Q.—Can you tell me of any person to whom you have administered treatment in their home during the past twelve months? A.—I haven't had a bed patient in the past twelve months.

Q.—How many patients are you treating at the present time? A.—I am treating five patients for charity's sake.

Q.—How many patients were you treating six months ago? A.—Well, that depends on what day that was, I think I was treating eight.

Q.—How many patients did you have twelve months ago? A.—About the same number.

Q.—How many did you have twenty-four months ago? A.—Well, now, that is a very hard question to ask, I mean to answer, I don't remember.

Q.—Approximately how many? A.—Oh, eight or ten.

Q.—Then the number of patients you have had during the past two or three years has been around eight or ten? A.—Eight or ten.

Q.—Ten would be the maximum amount or maximum number? A.—I may have had twelve or fifteen for a short time.

Q.—But you didn't treat them regularly? A.—Yes, I treated them twice a day as long as they were taking treatments.

Q.—How many patients did you have three years ago? A.—Eight or ten.

Q.—What do you say was the reason you quit the Holderness treatment? A.—I quit the Holderness treatment because I became dissatisfied about his not being willing to answer criticism.

Q.—You believed in advertising, didn't you? A.—No.

Q.—You did advertise? A.—I did advertise, but I don't believe in it.

Q.—Didn't you testify on March 8th, this year, in your deposition, that the reason you ceased to use the so-called Holderness treatment in May 1922 was because you weren't making enough to suit you? A.—That was after I sold out to Harris, I discontinued with Holderness, but was using his medicine, some time in March '22.

Q.—Didn't you testify yesterday you agreed with him, when you dissolved your relation with him, you would not use his treatment further? A.—I did.

Q.—Yet you did use it up to May 1922? A.—I bought medicine from him, that was the agreement.

Q.—Didn't you testify on March 8th, this year, that the reason you quit the Holderness treatment for tuberculosis in May 1922 was "I wasn't making enough money to pay for the medicine I had to buy from Holderness"? A.—That is a fact.

Q.—Then you were having your financial troubles in 1922, weren't you? A.—I wasn't having financial troubles, I wasn't making any money and I wouldn't continue.

Q.—Now, Dr. Brunson, do you know a man named Frank P. O'Hara? A.—The stool pigeon that was sent down here? O'Hara? A.—I have asked you if you know a man named Frank P. O'Hara? A.—I do.

Q.—You treated him in May and June of 1938, did you not? A.—I treated him for forty-five days in May and June.

Q.—How much did he pay you? A.—He paid me at the rate of \$60 a month.

Q.—That was \$120 or \$90 that he paid you for the entire treatment? A.—He paid me \$120 and I sold him two bottles of medicine, and gave him credit on the two bottles of medicine for \$30.

Q.—The bottles of medicine you gave him were six ounce vials? A.—What is that?

Q.—The bottles of medicine you gave him were six ounce vials? A.—Yes, sir.

Q.—And, in addition to that, when he made a little trip to Chihuahua you gave him some additional medicine in a small bottle? A.—I did what?

Q.—You gave him some additional medicine in a small bottle? A.—When he went down in Mexico, I wanted him to continue the treatment, and I gave him enough medicine to fill his atomizer; he didn't intend to be gone but about four days.

Q.—How much did you give him at that time? A.—I suppose about an ounce or ounce and a quarter.

Q.—The other two bottles you gave him about the 24th of June 1938? A.—The evening before he left.

Q.—They were true solutions of yours? A.—It was the same solution.

Q.—Exactly the same solution you used then and use now? A.—Same solution.

Q.—How long have you been using that identical solution? A.—I have been using it since the first part of July 1922.

Q.—You did, in addition to furnishing him with some vials of the solution, sell him some equipment or have him purchase some equipment? A.—He asked me to purchase for him an oxygen gage and other paraphernalia that went with it, so that he could buy a tank of oxygen when he got to Chicago and continue the use of the medicine.

Q.—Do you know what was paid for that? A.—\$24 and something.

Q.—He paid you all together somewhere around 160 odd dollars, did he not? A.—I think a little more than that, buying that outfit for him.

Q.—The outfit that you did equip him with was the same that—the same character of equipment that you use? A.—It is the same I use in my office.

Q.—Same manufacturer? A.—I don't know whether the same manufacturer, it was an oxygen gage.

Q.—You recommended it to him? A.—Yes.

Q.—Of what did that equipment consist? A.—Well, I just told you, an oxygen gage, rubber hose and a cutoff, and a cutoff that fits in the atomizer point, that is all there is to it.

Q.—Was that gage a pressure gage? A.—It controls the pressure.

Q.—What pressure do you use in connection with administering this treatment? A.—From 35 to 40 pounds.

Q.—From 35 to 40 pounds per square inch? A.—What is that?

Q.—What do you mean by 35 to 40 pounds? A.—Some I use just 35 pounds, some 40, some patients don't like for it to be such hard pressure.

Q.—Thirty-five to 40 pounds per square inch, is that the pressure? A.—That is the way it is figured.

Q.—You blow this vapor into the mouth or nostrils at a pressure of 35 to 40 pounds? A.—That is in the mouth.

Q.—What pressure do you use in the nostrils? A.—I use about from 5 to 7½ pounds.

Q.—Did you have any of your patients use your treatment in their homes, administer it themselves? A.—Yes.

Q.—Whom did you have here in El Paso any time making use of your home treatment within the past two years? A.—Well, I have had a good many of them.

Q.—In the past two years? A.—Yes.

Q.—In their homes? A.—Yes.

Q.—Who were they? A.—Fred Knollenberg, Mr. H. P. Talley, Mr. Lozier. Those treatments were for colds and sore throats.

Q.—They weren't for tuberculosis, then? A.—No.

Q.—What are the symptoms of tuberculosis? A.—I answered that yesterday afternoon.

Q.—You answered in response to your own counsel.

The Court:—The question he asked may be answered.

Q.—What are the symptoms of tuberculosis? A.—Different people have different symptoms; usually the first symptom they begin feeling bad in the afternoon, in a short time they begin coughing, as soon as the pus germs become active they begin running temperature.

Q.—What else, what other symptoms do they have? A.—What other symptoms?

Q.—Yes. A.—Expectorating mucus and pus, and the tubercular bacilli in the sputum.

Q.—What are the objective—are those all objective symptoms? A.—All except the sputum examination.

Q.—How do you distinguish between objective and subjective symptoms? A.—What is that?

Q.—How do you distinguish between the terms objective and subjective when you refer to symptoms? A.—Well, the objective symptoms are the symptoms that you see when you look at a person over, the other is x-ray or microscope.

Q.—Do you classify what you find in the sputum as objective or subjective? A.—That is subjective; it could be both subjective and objective.

Q.—What do you mean by that? A.—What do I mean?

Q.—What do you mean by saying it could be both? A.—Well, the objective symptom is examining the sputum and finding the germ, the subjective symptom for that particular examination is about the same thing.

Q.—Then the subjective and objective symptoms are the same in that instance? A.—No, not always, but in that particular case they are.

Q.—When are they different? A.—Well, for instance, if you examine a person, have a sputum examination, and don't find tubercular bacilli, still they are running every symptom of tuberculosis, many, many patients are treated for tuberculosis and you never find the tubercular bacilli.

Q.—Generally speaking, what is a subjective symptom? A.—It is an examination you make by stethoscope, examination you make by palpation.

Q.—Isn't that objective? A.—Well, I don't know.

Q.—Can you just distinguish now, Doctor, to us the difference between objective and subjective symptoms, as a physician? A.—I can't give the exact definition of them.

Q.—You have been practicing medicine how long? A.—Forty years.

Q.—And can't tell this court and jury the difference between subjective and objective symptoms? A.—I don't think that has anything to do with the case.

The Court:—In the first place, counsel will not argue with the witness. The witness will not undertake, in answer to a question, to say that has nothing to do with the case, whether you should answer the question or not.

Witness:—I beg pardon, Judge, I didn't know it.

Q.—Now, Doctor, you can't tell us the difference between subjective and objective symptoms? A.—I don't know that I can give the difference, but I can examine a patient and tell you about it.

Q.—You don't want to undertake to tell us what subjective symptoms are? A.—Will you put that down that I can't answer that question.

Q.—You want to put it down you can't answer what objective symptoms are? A.—I told you what the objective symptoms were.

Q.—You also want to put it down that you can't distinguish between objective and subjective symptoms? A.—I can't give you the definition exactly.

Q.—You can't distinguish between the two? A.—Can't do what?

Q.—I say, you can't distinguish between the two? A.—Yes, objective symptoms are the symptoms you get from observation and examining your patient with a stethoscope. Subjective symptoms are your temperature and finding the tubercular bacilli in the sputum.

Q.—All right, can you see the tubercular bacilli in the sputum? A.—What?

Q.—Can you see the tubercular bacilli? A.—Put under a microscope I can.

Q.—You can't see it with the naked eye? A.—No.

Q.—Can you tell anything about whether there are bacilli in the sputum with the naked eye? A.—Absolutely not.

Q.—Have you a microscope in your office? A.—No.

Q.—Then you don't make any analysis or examination of the sputum yourself? A.—No, I have that done at the laboratory.

Q.—What other diseases do you treat besides tuberculosis, colds and bronchial troubles? A.—I treat any disease of the lungs or throat with the exception of cancer.

Q.—Do you classify yourself as a tuberculosis specialist? A.—I think I am.

Q.—How long have you been so classifying yourself? A.—How long what?

Q.—How long have you been so classifying yourself? A.—Since 1920.

Q.—Is there a slight cough in all cases of tuberculosis? A.—Is there what?

Q.—You testified a cough was one of the symptoms of tuberculosis? A.—Yes.

Q.—Is a cough always a symptom? A.—I don't think I have ever seen a patient that didn't cough.

Q.—Would you then say a cough is always a symptom? A.—Yes—you can have a cough from bronchitis just the same as from tuberculosis.

Q.—But a cough is always a symptom of tuberculosis? A.—Yes.

Q.—What are rales? A.—What are rales?

Q.—Yes. A.—All right, I can explain that to you. The secretion comes into the air cells and, at the end of expiration, those cells close; when there is an inspiration, they are pulled apart to let the air in and it makes a cracking sound.

Q.—How do you classify rales? A.—You mean the different kinds?

Q.—Yes. A.—We have a subcrepitant rale, that comes from the air cells.

Q.—What is that? A.—One that makes a crepitant sound, just like pulling fly paper apart, you can hear the air going in and the cells open.

Q.—That is the way you illustrate what constitutes a crepitant rale? A.—Yes.

Q.—What other kinds of rales are there? A.—Crepitant, subcrepitant, mucous rale.

Q.—What is a mucous rale? A.—A mucous rale is in the larger bronchial tubes, you can hear that when breathing and the lung is full of secretion.

Q.—What is a cell? A.—What?

Q.—What is a cell? A.—A cell?

Q.—C-e-l-l. A.—That is an opening, air cell, a small microscopic opening in the lung.

Q.—How do you say that those cells operate in the case of a crepitant rale? A.—When you have a crepitant rale, those cells, where the lung is affected, where it has pus in the lung, at the end of inspiration I told you that they folded up, and on expiration they open, and pulling that sticky mucus and pus apart makes a cracking sound.

Q.—What is a subcrepitant rale? A.—That is in the air vesicle.

Q.—What is an air vesicle? A.—An air vesicle is a part that contains air when you breathe it down.

Q.—Is there any distinction between that and a cell? A.—Well, it is the same thing.

Q.—Have you ever treated a case of tuberculosis of the larynx? A.—What?

Q.—Tuberculosis of the larynx? A.—Of the larynx?

Q.—Yes. A.—Yes.

Q.—What is the larynx? A.—The larynx is part of the throat, the larynx and pharynx, and the pharynx enters in the trachea and the larynx into the esophagus.

Q.—How do you determine whether a person has a case of tuberculosis of the larynx? A.—What?

Q.—How do you determine whether a person has a case of tuberculosis of the larynx? A.—You can see the tubercles that are formed by the tubercular bacilli.

Q.—How do you see them? A.—How do I treat them?

Q.—How do you see them? A.—Oh, the tubercles that are formed are not hard to see, you can see those with the naked eye.

Q.—How do you treat that kind of a case? A.—I treat it with medicine, just like tuberculosis, except I spray the throat more than I give inhalation.

Q.—You don't give them inhalation so much for tuberculosis of the larynx? A.—I do, I give inhalation because they always invariably have a lung infection when they have tuberculosis of the throat.

Q.—The treatment in the case of tuberculosis of the larynx is sort of direct application? A.—I give direct application and you might say indirect application.

Q.—What do you mean by direct application? A.—In direct application they do not breathe while I am spraying the throat.

Q.—How do you examine the larynx? A.—How is that?

Q.—How do you examine the larynx? A.—You can use a tongue depressor and look at it.

Q.—You look at it with your own eye, open the mouth and look at it? A.—Yes, and if I am very doubtful if they have tuberculosis I get some of the mucus accumulated in the larynx and put it under a microscope.

Q.—Do you do anything else in connection with the examination of the larynx? A.—That is all that is necessary.

Q.—You would call that a complete examination? A.—Yes.

Q.—How do you say you recognize such cases? A.—What?

Q.—How do you say you recognize such cases? A.—You mean tuberculosis of the larynx?

Q.—Yes. A.—You can see the tubercles and they have inflamed, red, fiery throats, very sore; usually they run a high temperature, higher with tuberculosis of the throat than with tuberculosis of the lung.

Q.—And how long a time do you treat those cases? A.—Until they get well.

Q.—How long does that take? A.—That all depends on how bad the condition is. That is the hardest form of tuberculosis to treat.

Q.—What is the general length of time you would say you would take in a case of that sort? A.—I did not understand.

Q.—What is the general length of time you would say you would take in a case of that sort? A.—I have not treated very many cases of tuberculosis of the throat. We do not have near as many cases as we do tuberculosis of the lung. I have treated cases and never did them any good at all. I have treated cases where they apparently got well.

Q.—We have discussed crepitant, subcrepitant and mucous rales. What other kinds are there? A.—There are a number of different rales.

Q.—Name some of them. A.—Crepitant, subcrepitant, mucous, sonorous.

Q.—What is a sonorous rale? A.—That is kind of a musical rale.

Q.—How do you distinguish between those four classes of rales you have mentioned? A.—That is not hard to do. In the sonorous rale you get a musical rale. You hear the mucous rale in the small bronchi, and the crepitant in the still smaller and the subcrepitant in the air cells or vesicles.

Q.—What instrument do you use? A.—Stethoscope.

Q.—You likened the stethoscope, yesterday, to a telephone did you not? A.—As far as hearing is concerned, yes.

Q.—The difference between the two is in one instance the stethoscope only conveys sound and the telephone conveys and magnifies sound? A.—I only meant in hearing well.

Q.—Then the stethoscope does not operate like a telephone in amplifying sound? A.—It makes the sound much louder in using the stethoscope. Up to about 1900 we did use just our ear and there is not much better than that now.

Q.—You think there is nothing better than your hearing to determine those factors? A.—I can tell them.

Q.—What other rales? A.—I can't name all of them. I have named the important ones.

Q.—You cannot at this time give me the names of more than those four, the crepitant, subcrepitant, mucous and sonorous? A.—That covers the field.

Q.—Can't you think of any other at the present time? A.—I think that covers the whole thing.

Q.—How do you distinguish the difference between tuberculosis and silicosis? A.—What is that?

Q.—How do you distinguish the difference between tuberculosis and silicosis? A.—In tuberculosis you find the germ and silicosis, that is a disease that is caused from breathing microscopic parts of stone. A stone worker.

Q.—How do you distinguish whether a person has tuberculosis or silicosis. A.—What?

Q.—How do you distinguish whether a person has silicosis? A.—We get that a great deal from the history and symptoms. In silicosis before the tuberculosis manifests itself or the pus germ becomes manifest they do not run a temperature. They have labored respiration.

Q.—But, Doctor, you still have not told how you distinguish between the two. A.—I have told you in the case of silicosis they do not run a temperature until they develop tuberculosis or until the pus germ becomes prevalent and they begin absorbing pus. Then the diagnosis is a little bit hard to make unless you have the history of those cases.

Q.—You say in silicosis they do not run temperature? A.—They run temperature when they become infected with pus. Pus is the only thing that causes you to run temperature.

Q.—Didn't you say a while ago that tuberculous patients also run a temperature, that was one of the determining symptoms? A.—They do for a certain length of time. I have had patients for a number of years that did not run a temperature; they were subnormal.

Q.—Do you make the statement it is a fact that a silicosis patient does not run temperature and that is the distinguishing fact in tuberculosis? A.—I have never treated a case of silicosis, only read of it.

Q.—You do not know from actual experience about silicosis? A.—No, but I could detect it.

Q.—Do you know whether they have rales in silicosis? A.—You have rales after the mixed infection begins.

Q.—But not until that time? A.—You get a wheezing sound, something on the order of asthma.

Q.—The only difference in one instance they run temperature and the other they do not? A.—In silicosis they will run temperature as soon as it becomes infected with the pus germ.

Q.—How do you distinguish between silicosis and tuberculosis before that stage is reached? A.—That is very easy. You get that as he makes a wheezy sound.

Q.—Do you rely on the subjective or objective symptoms? A.—I rely on both.

Q.—Pneumonitis gives the same symptoms as tuberculosis or silicosis? A.—Are the symptoms the same?

Q.—Pneumonitis gives the same symptoms as tuberculosis or silicosis? A.—It differs as I told you.

Q.—I am now asking about pneumonitis. A.—The symptoms of silicosis—

The Court:—The witness does not understand the question.

Q.—What are the symptoms of pneumonitis? A.—That is pneumonia.

Q.—How do you distinguish between that? A.—If you have a typical case of pneumonia you first have a consolidation, a large chill, a temperature, you have a consolidation of the area affected, you have pleuritic pain.

Q.—What is the difference between what you have now described and a chronic inflammation of the lung? A.—You mean a chronic inflammation from what disease?

Q.—Inflammation of the lung. A.—I have not that clear.

Q.—What is the difference between what you have now described and a chronic inflammation of the lung? A.—A chronic condition is a condition that lasts quite a while and an acute condition when it first begins.

Q.—And that is the distinction you want to make at the present time, you want to rest upon that distinction at the present time? A.—Yes.

Q.—Do your patients need rest after the temperature becomes normal? A.—They need more rest than a well person would need, yes.

Q.—What is a fibrosis of the lung? A.—Fibrosis condition.

Q.—Fibrosis? A.—That is where fibrin forms in the lung.

Q.—What causes it? A.—Tuberculosis.

Mr. Sweeney:—If it please the Court, Dr. Fishbein is talking loud enough for me to hear him on the questions he is suggesting to the counsel. I can hear him clear over here. I suggest he talk in a lower tone of voice.

The Court:—He may be seated in such a manner with counsel at the table so that the jurors will not hear him. He may, of course, have the privilege of making suggestions to counsel as to questions that may be asked but in a manner not to be heard by the jurors.

Q.—Does tuberculosis produce fibrosis of the lungs? A.—Yes.

Q.—Is there anything else that produces it? A.—Pus infection will do it.

Q.—Could any other condition that produces fibrosis in the lung cause these same conditions you describe? A.—I will have to ask you to repeat.

Q.—Could any other condition that produces fibrosis in the lung cause these same conditions you describe; do fibrotic changes in the lung cause the same symptoms you have described? A.—Any other disease that causes fibrotic condition of the lung other than I described?

Q.—Yes. A.—I don't know any other.

Q.—You do not think it is difficult to tell the difference in different kinds of rales? A.—A person who has had experience, it is easy to tell.

Q.—What do coarse rales signify? A.—That is a crepitant rale you might say.

Q.—What is a sibilant rale? A.—I have answered that before. That is a musical rale.

Q.—You say the coarse rale is the same thing as a crepitant rale? A.—Yes.

Q.—What does it signify? A.—It signifies they have an infection, there is a poison, infection in the lung.

Q.—And what does a sibilant rale signify? A.—The same thing.

Q.—They both amount to the same thing? A.—They both show there is an infection.

Q.—Yesterday you said your gross income for 1938 was \$1,795? A.—It was \$1,795.50 if you want it accurate.

Q.—You testified on March 8th of this year that since 1930 or 1931 your gross income had never exceeded \$3,000 in any one year did you not? A.—From '31?

Q.—Yes. A.—No, it was more than that in '31 and in '32.

Q.—Didn't you testify on March 8th this year in your deposition since '30 or '31 your gross income had never exceeded \$3,000?

Mr. Quaid:—If Your Honor please, I think that that is the wrong way to refresh the witness's memory. If it is a question of impeachment he ought to ask the question of March 8th and give the answer and see if the witness wants to testify to that now. I think it is the wrong line of testimony.

Mr. Brown:—He is a party to the case.

The Court:—He is a party to the suit and the deposition having been taken when he refers to testifying on a certain date the witness himself also refers to the time the deposition was taken. It would be a more regular form of procedure to ask him a question and then have his answer to the question and then if his answer to the question is of such a character he may read the question and answer.

The Witness:—May I ask a question?

The Court:—Go ahead.

The Witness:—I can get my pass book and give it accurately every year if that is what they want. Answering from memory is very hard to do.

The Court:—The answer you just made will go in the record.

Mr. Brown:—I understand the Court overrules the objection?

The Court:—Oh, yes. The Court realizes there is something in the exception, that there is a little better form of procedure and counsel may bear in mind the Court's comments.

Q.—You have not paid any income tax since 1930 or 1931? A.—I do not think I have paid an income tax since '32.

Q.—Did you testify in March of this year that you had not paid an income tax since 1930?

The Court:—There you are asking to what he testified on a certain date, a certain question and certain answer, if counsel wants to object along that line—

Mr. Quaid:—We object.

Mr. Brown:—In order that I may understand the matter, does the Court— is the ruling of the Court that I have to ask him with reference to each specific year?

The Court:—If you seek to impeach him.

Mr. Brown:—As I understand a party to a suit, any statement he makes whether under oath or not is admissible in evidence. The same condition does not exist for a party who is not a party to a suit and one who is a party to a suit.

The Court:—The ruling will stand.

Q.—What was your income in 1935? A.—If you will let me get my cash book I can give it accurately.

The Court:—If you are able to give it substantially, all right; otherwise you may get your cash book and at another time be examined about it. If you are in a position at this time to state substantially do so, otherwise at some later time in connection with the case you may do so; not that we will recess at this time for that purpose. If you want to have your books present you may have them. You can have the books here this afternoon.

Q.—I will ask this question with reference to his testimony: On March 8th of this year, didn't you testify under oath in taking your deposition that you made \$2,100 gross in 1935? A.—I think that is as near as I can get it.

Q.—Didn't you undertake at that time, naming specific years, to state what your income was independent of your books? A.—I was giving it to the best of my memory.

Q.—To the best of your memory in 1935 your income was around \$2,100 gross? A.—Yes.

Q.—And in 1936 it was around \$2,600? A.—'36?

Q.—Yes. A.—Yes.

Q.—You were asked to produce copies of your income tax reports, Dr. Brunson? A.—All that I have I can produce them.

Q.—We asked you to produce them at that time did we not? A.—I do not think so.

Q.—Don't you recall we gave you specific notice to produce income tax reports since '31 and '32? A.—I can produce them.

Q.—You declined at that time to produce any? A.—I do not remember I did.

Q.—Where are they now? A.—I can go to my office and get a few of them. I do not know that I can get them all.

Q.—You have not brought them down here? A.—No.

Q.—Do you regard it as ethical for a physician to keep his secret formula? A.—What is that?

Q.—Do you regard it as ethical for a physician to keep his secret formula? A.—Medical ethics are ethics that are laid down by the American Medical Association. I am not a member of the American Medical Association and as long as I conform to the laws of the state of Texas I do not think that is unethical.

Q.—Do you think it is ethical for a physician to advertise, publish testimonials in the paper? A.—If he cannot get before the public any other way, and he is libeled, every mean thing said against him, that is the only way he can get before the public and that conforms with the state laws of Texas.

Q.—Then you think it is perfectly proper for a physician to advertise? A.—If he belongs to the American Medical Association he would get fired for advertising, but I did not belong.

Q.—I am not asking you that. I am asking do you think it is perfectly proper, in conformity with ethics, to advertise? A.—It was distasteful to me to advertise and I would not have advertised if I could have gotten a perfectly square deal with a scientific investigation. It was my intention to give my formula to the public to the people suffering from tuberculosis, all the people suffering from it in the world, but I did not intend to give it up until I got that scientific investigation.

Q.—You did advertise your treatment rather extensively in the papers? A.—You mean here?

Q.—Here in El Paso? A.—Yes.

Q.—And you advertised various remedies and treatments in Arkansas when you were there? A.—I did not. They don't belong to me.

Q.—Do you recall a remedy known as Dr. Brunson's Famous Prescription? A.—Yes. A splendid prescription.

Q.—Did you advertise that? A.—I did not, a drug store did.

Q.—Did you allow them to? A.—I told them they could; even if you were a member of the American Medical Association you could do that.

Q.—You first had an arrangement with Reinberg and Collier for advertising and dividing the receipts did you not? A.—I gave them permission to advertise Brunson's Famous Prescription only.

Q.—And you were to get a percentage of it? A.—That is what I understood at the time.

Q.—Did you authorize Seawell's to advertise Brunson's Famous Prescription? A.—I did.

Q.—You personally wrote a recommendation or advertisement on a prescription slip and turned it over to them for that purpose did you not? A.—I did.

Q.—Signed your name to it? A.—Yes.

Q.—And that appeared in the Arkansas paper in Pine Bluff? A.—Only in the Pine Bluff paper and that was put in and paid for by Seawell's Pharmacy.

Q.—It was put in singly and also put in connection with an advertisement of the prescription? A.—I did not catch that.

Q.—I show you what is marked Defendants' Exhibit No. 10, with this notation for identification M. M. F. 3/8/39, and ask if you ever saw that before and to identify it? A.—That is my signature.

Q.—That is a photostatic copy of the instrument you wrote? A.—For Seawell's Pharmacy and there is nothing wrong about it.

Q.—And that appeared in the Pine Bluff Commercial did it not, a newspaper published at Pine Bluff, Arkansas? A.—Yes.

Q.—You authorized the publication of that? A.—I authorized Seawell to put it in if he wanted to.

Mr. Brown:—We offer this in evidence.

The Court:—There being no objection, it will be received.

The advertisement was then received in evidence, marked Defendants' Exhibit No. 2, was read to the jury and is in words and figures as follows:

From Page 2 March 7th 1917 Pine Bluff Commercial

SEAWELL'S PHARMACY

Phone 45

224 MAIN STREET

For Any One
troubled with indigestion, disorders
of the stomach, liver, kidneys or in
general run down condition—

"Dr. Brunson's Famous Prescription"

(Price one dollar)

Reg. No. Date 191

Asa Brunson M. D.

Have This Filled at SEAWELL'S—I

may want to refer to it.

"The home of the ONLY GENUINE Dr. Brunson's
Famous Prescription."

Q.—Also, this other instrument marked Defendant's Exhibit 11, for identification M. M. F. 3/8/39, containing a copy of the same instrument? (Handing it to witness.) A.—That is the same thing.

Q.—And you knew about that advertisement? A.—I did not have anything to do with that. I knew they were getting it out and it was without my permission.

Q.—And it was advertised in that way? A.—It was advertised as Dr. Ran Brunson, my uncle.

Q.—You signed the document? A.—I signed the instrument.

Mr. Quaid:—Your Honor, we want to object to all that portion of the advertising below Dr. Brunson's signature. It shows that is a reprint of what has been introduced in evidence, but below that shows that is was Dr. Ran Brunson's formula. We would not be bound by advertising of the Seawell Pharmacy.

Mr. Brown:—It appeared in connection with the advertisement.

The Court:—As I understand the testimony of the witness, the witness testified that he knew that advertisement was being run and interposed no objection to it being run but he made his explanation of his signature. Overrule the exception.

Mr. Quaid:—I thought it was run without his consent.

The Court:—Interrogate him further, Mr. Brown.

Q.—Do you recall ever having made the statement that you did see this advertisement? A.—I don't know whether I stated that I didn't remember whether I saw it or not, but I suppose that I did.

Q.—You took the Pine Bluff Commercial and read it every day, did you not? A.—What?

Q.—You took the Pine Bluff Commercial, the newspaper; you took the Pine Bluff Commercial and read it? A.—Yes.

Q.—You knew about the contents of the advertisement that was being published in it? A.—No, I very seldom read advertisements in the paper; I was very busy. I would read the news. I knew they were advertising, but I don't know that I paid much attention to it. They had a scrap there about three or four months.

Q.—You say you saw this advertisement? A.—I may; I don't remember it.

Q.—You won't deny it? A.—I won't deny it, no.

Q.—You never did make any protest about this advertisement, did you? A.—Not to Seawell's Pharmacy I did not.

Q.—In fact you testified you authorized the publishing of this prescription and that advertisement because you wanted to get even with Reinberger & Collier? A.—Yes; we had a fight.

Q.—That was the reason for publishing this stuff in the paper? A.—That is the reason Seawell people put it in. I knew he was going to advertise, but I didn't know that he was going to put that in. If any one came in and wanted to know if it was good, and it was good.

Q.—You turned it over to him? A.—I turned it over to him to use as he saw fit.

Mr. Brown:—We now offer this, if the Court please.

The Court:—The Court overrules the exception.

Mr. Quaid:—Note our exception.

Said document was then received in evidence, marked "D-3" (fig. 1).

[Mr. Brown read the exhibit to the jury.]

Q.—And that advertisement appears with your name at the bottom? A.—My name? Oh, he put my name at the bottom, yes; I was the originator of that prescription.

A recess was taken at 10:35 a. m., and on reconvening at 10:50 the following proceedings were had (being in the absence of the jury):

The Court:—The Court was informed that defendant's counsel have some authorities they would like to present to the Court at this time bearing on the question as to whether or not the plaintiff in this action should be required to reveal his formula. I can hear those at this time, or the Court can hear them later. The Court is reserving that question. The witness is off the stand, and counsel for defense will be protected in ruling on that question by the Court reserving such matter. Counsel for the defendant may recall or have again placed on the stand the plaintiff, to be interrogated with reference to the formula, and the Court making ruling at that time.

Mr. Brown:—If Your Honor please, the general rule—

The Court:—The Court anticipated counsel would probably have some other authorities to present to the Court than yesterday and therefore is reserving such matter for further consideration.

Mr. Brown:—The general rule appears in Corpus Juris, with citation of certain specific cases, one of which we have here, which we think is practically on all fours.

The Court:—If you haven't that brief prepared, Mr. Lassetter, you may take this down.

Mr. Brown:—"Where a trade secret is relative to an issue and disclosure essential to a correct determination, a witness is not privileged to refuse to disclose it." That appears under the title "Witnesses" in 70 Corpus Juris, sec. 897, page 743, note 70. The author cites a decision of the California Court of Appeals, *Willson v. Superior Court of California*, in and for Los Angeles County, appearing in the 225 Pacific at page 881. We have also a reference to the 66 California Appeals, page 275. In that case a party had been injured by the use of a certain chemical which he claimed was a highly explosive and dangerous chemical. He brought suit for damages against the party, and the party on the stand testifying refused to divulge the contents of the formula or what the component parts of that mixture or explosive were. The lower court refused to require the party to divulge. The allegation was that it was a dangerous and highly explosive material, and denial was made of that. The party refused to divulge, and the lower court refused the right. It then went up to the Court of Appeals on a citation for contempt, and the Court held the party being a voluntary witness, this being a relevant matter under the pleadings in the case, he would be required to divulge the contents of that formula or what the ingredients were. We want to read now shortly from the opinion. The question was "What are the chemical constituents of that flare? And by that I mean what is the flare made up of? What are the chemicals or substances or drugs of which it is made, and what are their respective proportions?" The objection was made that it was incompetent, irrelevant and immaterial and calling for a privileged matter, a secret process or trade secret; and, further, on the ground that the disclosure of the trade secret is not necessary to the decision of this case, or in the interests of justice.

"On advice of counsel, defendant declined and refused to answer the question which had been propounded to him. The court adjudged him guilty of contempt of court for such refusal, and the defendant was thereupon committed to the county jail of Los Angeles County until he should answer the said question."

"The question of the jurisdiction of the trial court to so adjudge defendant guilty of a contempt of court and to order him committed by reason thereof is the only matter suggested for determination herein."

Fig. 1.—Reproduction (reduced) of a photostatic copy of an advertisement that appeared in the Pine Bluff Commercial, Feb. 6, 1917.

The Court then speaks of the general rule, and continues:

"It is important to determine, first, whether the allegations of the complaint were sufficient to authorize the reception of such evidence. Reverting to those allegations, it will be noticed that there are many expressions to the effect that the chemical constituency of the flare was 'highly and dangerously explosive.' The meaning of such language is apparent. There can be no misunderstanding that the thought thereby sought to be conveyed is that the substance of which the flare is composed is explosive in the same sense that gunpowder is. In plain and forceful language the defendant is placed on notice of just what plaintiff claims is one of the properties of the substance which defendant sold for plaintiff's use, without any alleged adequate warning as to its dangerous qualities. Should the ingredients of the flare, taken either separately or in any combination of its various parts, however prepared or however treated, be shown to be entirely harmless from an explosive standpoint, the case of the employee—"

The Court:—In the interest of time I don't think it is necessary to go into detail. You may state the authorities, and state what the facts are. The Court does not at this time wish to go into length on the authorities.

Mr. Brown:—The Court then continued, and held that he would be required to divulge, it was an essential matter, it was a relevant matter, that the pleadings raised the issue, and he could not resort to, especially being a party to the suit and having taken the stand, could not avail himself of the privilege on the ground that it was a trade secret, and required him to divulge the contents of that chemical or constituent.

Now there are quite a few cases in which injunctions have been sought to restrain the disclosure as to what the certain contents were or what a certain practice was, and a reading of those cases discloses in nearly all of them, in fact all of them as far as I am able to determine, there was some confidential relation which arose and the party was trying to enjoin a former employee from disclosing the formula, and the Court held under those circumstances he should not be required to disclose the secret, an entirely different situation than prevails at the present time.

There is another case, *Gossman v. Rosenberg*, Supreme Judicial Court of Massachusetts, 129 N. E. 424, which has some pertinent remarks. In that case it was in connection with trade practices and whether or not a party could be required to divulge who his customers were, and the Court held that was an issue in the case. The Court held the party could not fall back on the privilege and would be required to divulge. In the *Brinkley* case, if the Court cares for us to state how the matter arose—

The Court:—I don't know that the Court does. The Court probably has some general idea about that case, and I am going to hear from counsel on both sides. The Court is getting information as the case progresses that will aid and assist the Court in arriving at a definite conclusion of this. The Court is not going to be too hasty in ruling on it but is going to rule on it decisively before we get through with this case. If counsel on the other side have any further authorities to submit you may do so at this time. You gentlemen may prepare memorandum briefs if you wish to, to submit to the Court on the question.

Mr. Quaid:—Yesterday I stated the general proposition—

The Court:—Just in addition to what you had yesterday, if you have any authorities bearing on the matter.

Mr. Quaid:—I would just like to cite 138 S. W. page 352, *Stuckes v. National Candy Company*.

The Court:—What is the page?

Mr. Quaid:—Page 352, 138 S. W. page 352, *Stuckes v. National Candy Company*.

The Court:—What do you understand to be the facts in that case, and the holding in that case? You may just state it orally.

Mr. Quaid:—The facts were there were two outfits fighting over a candy recipe, and the defendant claimed certain rights growing out of transactions with the plaintiff. The plaintiff sued to stop the defendant from manufacturing their particular brand of candy, claiming it was an infringement of the trade secret and that they did not have a right to advertise that particular kind of candy. The plaintiff brought in a lump of their candy, and they brought in a lump of the candy of the defendant. I believe they call it dope or grease. And the plaintiff then moved that the defendant be required to disclose what was in their lump, and the Court held that that was not necessary; they had the lump and they could get an analysis from it.

The Court:—If this matter is brought in issue, and properly in issue, it was put in issue by the plaintiff in bringing his action here; the defendant is entitled to certain rights in his defense of the case. The plaintiff on the stand said you can't reach it by analysis. The Court might go ahead and rule on this matter at this particular stage of the proceeding but the Court feels as though the Court is perhaps gaining a little enlightenment as the case progresses, and is thrown on the proposition to enable the Court to determine more decisively on whether it should be divulged.

The jury thereupon returned to the jury box.

Questions by Mr. Brown:

Q.—Now, Dr. Brunson, this Dr. Brunson's Famous Prescription was really a laxative, wasn't it? A.—Was what?

Q.—Was only a laxative? A.—It was much more than a laxative.

Q.—What was it? A.—I will give you the contents. It was nitric acid, muriatic acid and iron, and saturated with a solution of epsom salts. Nitric acid affects the liver, muriatic acid is one of the natural contents of the stomach, is always good where there is lack of acids, and salts acts as a laxative, and that is what most people need.

Q.—So it was after all practically a laxative? A.—It was much more than that.

Q.—I believe you said that you had seen— A.—How?

Q.—I believe you said in March you thought you had seen this ad which I now show you? A.—I may have seen it, but

it has been so long ago, Mr. Brown, I can't remember it. That is twenty-three or four years ago.

Q.—Was it one of those run in the regular course by Seawell's Pharmacy? A.—Yes, it was run by Seawell's Pharmacy.

Q.—Under the arrangement which you had with them? A.—The arrangement I had with them was to put the medicine out to be sold and they advertised it.

Q.—You furnished it to them? A.—Yes, sir.

Q.—You furnished them with a public endorsement of it, did you not? A.—Yes, sir. I will endorse it now.

Mr. Brown:—We offer defendant's Exhibit 12 for identification, marked M. M. F., 3/8/39.

Mr. Quaid:—Just a minute.

The Court:—What is your objection?

Mr. Quaid:—My objection is it is too remote. The evidence indicates it is some twenty years ago. It is not relevant to this case, has no bearing on it in any manner.

The Court:—Let me see the ad.

Mr. Brown:—We are going to show a policy continuing on down into El Paso, Texas, in advertising.

The Court:—Well, counsel is aware of the rule of law perhaps that even evidence of a conviction for a felony, and this is a civil case entirely, reaches a stage of limitation.

Mr. Brown:—That is very true, Sir.

The Court:—I believe that limitation is around about twenty years. I am not going to worry very much about that now.

Mr. Brown:—It is a continuing policy with reference to the value and importance of his preparations, which we expect to continue on down to the present, until recent time, in El Paso.

The Court:—Does this relate to a large number of these matters?

Mr. Brown:—There are quite a number of them, if Your Honor, please.

The Court:—The Court will read a few. The Court will hear from counsel fully at this time, counsel for the defendant, as to a statement from them as to wherein this testimony is deemed material or will have a proper bearing and admissible on the issues here in controversy, as related by the pleadings in this case.

Mr. Brown:—Your Honor please, this is a libel suit in which the plaintiff himself, by coming into court, has put in issue his professional character and reputation, the ethics of the profession. We are not bound by his idea of ethics or by any individual's idea of ethics. We are bound by the ethics of the body of the profession itself. He claims to be a practicing physician and surgeon, doctor of medicine, of established reputation, and that that reputation was ruined and harmed by the publishing of certain defamatory matter on the part of or by the defendant. One of the elements of a man's reputation in his particular profession is whether or not he conforms to the ethics of the profession. We expect to connect this up on down into his career into El Paso County, or the city of El Paso, and show his advertisements of a similar character with reference to the particular preparation that is under investigation in this particular case. It shows the course of—

The Court:—The Court will say that matters of recent date, or along about the time of and preceding for a period of time in advance of the date of the telegram made the basis of the action herein, dated January 19, 1938, the Court will probably consider material. That presents a different question than the Court is here presented with at the present time; the matter that is running in the Court's mind at the present time is how far back you should go into the matter of this character. The Court sees these advertisements, methods of procedure, and so forth, determination of whether it is ethical or bearing on the question of reputation. The Court intimated to counsel a few moments ago that the matter that is running in the Court's mind is how far back you can go in matters of this character, as to the question of proper consideration as to its admissibility. The Court will ask you to address yourself to that phase of it.

Mr. Brown:—We understand, Your Honor please, there is a very, very wide latitude in a libel case, much wider than ordinarily in a case, and this bears on a continuing system of practice, which we will connect up, his advertisements in the county of El Paso since he has been residing here.

The Court:—That wouldn't need any following up probably.

Mr. Brown:—It is a continuing course though.

The Court:—What the Court is getting at speaks for itself. The Court will give wide latitude as to matters that may bear on any phase, and all facts and circumstances that enter into the question of whether or not the matter is libelous.

Mr. Brown:—May I say this much?—

EXTRA! EXTRA!

**DR. BRUNSON'S
FAMOUS
PRESCRIPTION**

"The Medicine of Merit"

Now Manufactured, Sold and Guaranteed by
Seawell's Pharmacy

To the Public:

The medicine known as Dr. Brunson's Famous Prescription is known by its trademark—The Fishbowl. It is a powerful and effective remedy for all the ailments of the human body. It is a powerful and effective remedy for all the ailments of the human body. It is a powerful and effective remedy for all the ailments of the human body.

Fig. 2.—Reproduction (reduced) of a photostatic copy of an advertisement that appeared in the Pine Bluff Commercial, Jan. 13, 1917.

The Court:—The Court has admitted two or three, some of these that have a name signed to. The Court is seeking to save a little time. A good many of these have his name signed to them, and several of them have not. They appear to be in some character of controversy up there in Arkansas between some drug concerns. I don't know whether that is all material here in this case or not. I want to let in all of that which is material and eliminate some of that matter that might not be.

Mr. Brown:—The plaintiff in this case gives as his reason for advertising the fact that he had a fight, he had to fight the other doctors, and that was one of the reasons he fell out with Holderness; yet we find they go back to a long period back of that time, when he did not have that excuse, and he was adopting the same course of procedure. He didn't have the excuse he had to fight the medical profession here in El Paso or the American Medical Association.

The Court:—Now, I am asking you to mark those that you are going to seek to offer here. Some of them have his name signed to them and some do not. And the Court, in the interest of time, is going to lump some of these matters. The Court made reference a few moments ago about a criminal case in which the question of reputation of a man arose. Counsel is familiar with those authorities in the state of Texas where it is sought to show that reputation had become involved. I remember very distinctly a case in one county in which Polk Moseley was a conspicuous figure, was up for horse stealing perhaps, or bootlegging in the United States Court, or something of that sort, and it was sought to prove about twenty-one or two years before that he was convicted of horse stealing. The Appellate Court of Texas held that was going too far back on the question of reputation. So that is all, gentlemen. The Court has admitted three or four of them already, and it seems as though that is rather cumulative, or along the same order.

Mr. Brown:—It contains one additional article that was not in the other. We expect to stop with this one and jump to 19—

The Court:—Just mark the additional ones you want to offer, and the Court will determine as to the admissibility of them.

Mr. Brown:—We only want and expect to offer of those in Arkansas this Exhibit No. 12. Later on when the question comes up on the testimony of another witness we may want to offer some others.

The Court:—For consideration of the Court at the present time, No. 12?

Mr. Brown:—Yes, sir.

The Court:—I will look at that.

Mr. Brown:—Particularly this portion of it (indicating to the Court), but to identify it we think it has to go in.

The Court:—This one bears the signature, a statement addressed to the public over the signature of Dr. Asa Brunson. The Court will overrule the exception and permit that instrument to be offered in evidence.

Mr. Quaid:—Note our exception.

The Court:—You understand the Court's ruling, Mr. Brown? The Court overrules the exception to that instrument, and the instrument may be offered in evidence.

Mr. Quaid:—We want our bill on that, and want our bill to show the approximate date of the advertisement.

Mr. Brown:—It shows in the body of it, above it, January 13, 1917.

The advertisement was thereupon received in evidence, marked "D-4" (fig. 2), was read to the jury by Mr. Brown.

Q.—Doctor, I just hand you this for the purpose of identification.

Mr. Quaid:—For the purpose of identification, that doesn't mean anything.

The Court:—He has handed it to the witness, to be marked for identification.

Mr. Brown:—We reserve our rights in that particular.

Q.—You have seen that before? **A.**—Yes.

Q.—It is marked "Defendant's Exhibit 19 for identification. 3/8/39. M. M. F." You have seen this? **A.**—Yes.

Q.—You knew about it at the time? **A.**—Yes, sir.

The Court:—What is its identification number here?

Mr. Brown:—It is marked "D-5," I just want to identify it.

Whereupon, said instrument was marked exhibit "D-5" for identification.

Q.—Do you identify the next pamphlet which I hand you, "The Atomizer," El Paso, Texas, February 1929? **A.**—This "Atomizer" was gotten out—

Mr. Quaid:—Ask him the question.

Q.—You have seen that before? **A.**—Yes.

Q.—That was published by you? **A.**—Published by my office.

Q.—Published in your office? **A.**—In my office, yes.

Q.—Edited by you? **A.**—Not by me, by the young lady in my office, my secretary.

Q.—You had it distributed? **A.**—She distributed them.

Q.—She was employed for that purpose? **A.**—No, she was employed as my secretary and stenographer.

Q.—These items set forth in the "Atomizer" were compiled by you? **A.**—This girl got them up, yes, sir.

Q.—The proofs were submitted to you? **A.**—No, I never saw it.

Q.—That document was distributed from your office and mailed out? **A.**—Yes, and there is nothing wrong about it.

Q.—You had more than 500 copies of it published and mailed? **A.**—No, we had—possibly it was 500, if I remember correctly, it was about 200 we got out.

Q.—Volume III, No. 2. You published "The Atomizer" over a period of six months or a year or two? **A.**—Longer than that, three or four years.

Q.—You knew about it? **A.**—Oh, yes.

Q.—And knew what its contents were? **A.**—Yes.

Q.—Was it published in furtherance of your business as a doctor? **A.**—No, it was for the amusement of my patients.

Q.—Didn't you identify this instrument in March of this year and state that your secretary obtained the information on which these articles were based from you? **A.**—Yes.

Q.—Didn't you state that you had seen this copy before? **A.**—I saw all of the copies.

Q.—Are you the Dr. Asa Brunson who is referred to in this document? **A.**—Yes.

Q.—Are you the one who is referred to as having originated a unique and successful treatment for tuberculosis? **A.**—Yes, sir.

Q.—And that you had become internationally famous on account of the results obtained in treating thousands of cases in all stages of the disease? **A.**—I didn't put that in there, it was written and being distributed before I saw it.

Q.—You knew it was in there? **A.**—No, I didn't.

Q.—Didn't you so testify before? **A.**—I read it after it had come out, and I stated it was too late for me to change it, there was nothing wrong about it, it didn't hurt anything anyway.

Q.—You permitted that document to be distributed at your expense? **A.**—Yes, I paid for having it printed and paid for the stamps and envelopes to send it out.

Q.—It was distributed by handing it to parties and by sending it through the mails, is that correct? **A.**—I sent it through the mails, and I was not breaking any law.

Mr. Brown:—We have decided to offer this instrument in evidence at the present time.

Mr. Quaid:—No objection.

Whereupon, said instrument was marked Exhibit D-6 and reads as follows, to wit:

**"THE ATOMIZER
Sprays all News**

Office of Publication

717-721 Caples Building

Volume III

El Paso, Texas, February, 1929

No. 2

**DR. ASA BRUNSON DISCOVERS TREATMENT FOR
TUBERCULOSIS EIGHT YEARS AGO.**

"Dr. Asa Brunson of El Paso who originated a unique and successful method for the treatment of tuberculosis, eight years ago has become internationally famous on account of the results obtained in treating thousands of cases in all stages of the disease.

"The doctor, who has been practicing medicine for thirty years is a graduate of the Memphis Hospital Medical College class 1899. He served as captain in the Medical Corps during the world war and for eight years has limited his practice to the treatment of tuberculosis exclusively.

"Dr. Brunson attributes his success in the treatment of tuberculosis, where other doctors have failed, to the fact that they have been constantly trying to eradicate the tubercle bacilli instead of the pus germs which he believes are entirely responsible for the bad symptoms of the disease.

"His theory of tuberculosis is that the pus germ plays a much more important part in the disease than the tubercle bacilli and he has proved conclusively that when the pus can be eliminated and the pus germs rendered inactive, patients even in advanced stages of tuberculosis recover very rapidly.

"The treatment is administered by means of inhalation and causes no irritation or reaction and the patient is not confined to a sanitarium or hospital but simply visits his suite of offices twice daily for treatment, when convenient, however, Dr. Brunson's treatment may be taken by the patient at home and at the present time the doctor is mailing medicine to patients from coast to coast and from the Canadian border to the Gulf of Mexico.

"Hundreds of tubercular patients who have taken Dr. Brunson's treatment have returned home and resumed their former occupations in all walks of life. Their letters of appreciation and recommendation flow into the office daily and it is a source of great satisfaction to the doctor to know that tubercular sufferers who once had little hope now enjoy the best of health.

"Dr. Brunson is offering to disclose his formula to the world after a ninety-day, scientific investigation by the medical association or any other scientific research foundation or organization and inasmuch as there are millions of cases of tuberculosis in the United States and the death rate is larger than from any other disease, it would seem vitally important that such an investigation be started immediately in order that those suffering from tuberculosis throughout the entire world might take immediate advantage of Dr. Brunson's successful method of treatment, especially since he offers to pay all expenses of such an investigation."

"OUT OF WORK FOUR YEARS,
SPENT THOUSANDS OF
DOLLARS, CURED IN
THREE MONTHS

Roswell, New Mexico,
December 1, 1926.

"I came to El Paso two years ago with an advanced case of tuberculosis. I had been sick for three years at that time. I took the sanatorium treatment for fourteen months, had a hypodermic every day and after this length of time, my doctor found a great deal of tuberculosis left in both lungs, and told me not to be out of bed more than three hours a day and not to walk out of the house.

"After being in idleness for over four years, and spending thousands of dollars for different treatments, I felt very discouraged. Then I decided to try the Brunson treatment.

"I took two treatments a day and at the end of three months I was cured. Then I made a trip back to New York and caught a bad cold and when I got back to El Paso my lungs were in bad shape again.

"I took the Brunson treatment again, and in three weeks my lungs were clear, and I am well and working every day.

"It is a great pity that the Brunson treatment and its wonderful results are not known far and wide over the world for many tubercular patients could regain their health and live useful lives after taking this treatment.

Mr. Frank Ehret."

Q.—717-721 Caples Building, those were your offices? A.—Yes, sir.

Q.—"Treating thousands of cases in all stages of the disease," is it true you had become internationally famous? A.—I didn't know that before.

Q.—Is it true you had treated thousands of cases up to 1929? A.—No, I hadn't treated that many—I may have treated that many.

Q.—In spite of the fact that you hadn't treated that many and hadn't become internationally famous, you allowed this to go out? A.—I didn't become internationally famous until my treatment was quoted as a dangerous fake.

Q.—You now claim to be internationally famous? A.—Yes, very famous.

Q.—Is Mr. Frank Earhart, mentioned in this testimony and this document the same Frank Earhart of Roswell, New Mexico? A.—That isn't his name.

Q.—What is it? A.—Frank Ehret.

Q.—Is he the same Frank Ehret to whom you wrote the letter about paying \$20 for each patient? A.—I paid him—

Q.—Just answer the question, is he the same person? A.—That I sent the \$20 check to?

Q.—Yes. A.—He is.

Q.—I hand you a pamphlet headed in large letters "TUBERCULOSIS. Asa Brunson, M.D. Practice limited to tuberculosis. Office 717 Caples Building, El Paso, Texas," marked originally "Defendant's Exhibit 21 for identification. M. M. F. 3/8/39." I will ask you if you didn't publish that document? A.—Yes, I published it and it is true.

Q.—When was that published? A.—That was published some time in 1929.

Mr. Brown:—We want to have it marked for identification Exhibit D-7. Whereupon, said instrument was marked for identification Exhibit D-7.

Q.—I believe you published about 500 copies of that, more or less, and distributed them through the mails and otherwise, did you not? A.—Yes.

Q.—Who compiled the data for this Exhibit D-7? A.—My stenographer and myself did the compiling.

Q.—I hand you in a folder marked El Paso Times, Sunday, August 17, 1924, a sheet, and ask you if you have seen that before? A.—Yes, I put that in and paid for it.

Q.—That is one of your paid advertisements, is it? A.—Yes.

Mr. Brown:—Will you mark that for identification.

Whereupon, said instrument was marked Exhibit D-8 for identification.

Mr. Quaid:—No objection.

Mr. Brown:—We are not offering it at the present time, we reserve the right, as I did before.

Q.—I hand you another folder with a portion of a page from a newspaper, El Paso Times, Sunday, August 31, 1924, and ask you if you have seen that before? A.—I have.

Q.—That is your advertisement? A.—Yes.

Q.—You prepared it and had it put in the paper and paid for it, is that correct? A.—Yes.

Mr. Brown:—Mark that for identification.

Whereupon, said instrument was marked Exhibit D-9 for identification.

Q.—I hand you another clipping from a newspaper advertisement with "Asa Brunson, M.D. First National Bank Building" on it, it is No. 4 of a series in the El Paso Times of June 15, I suppose '24, but I can't tell, did you ever see that? A.—I did. Percy Montgomery was the man who wrote it, it is a good ad.

Q.—It is your advertisement? A.—Yes

Q.—You paid for it? A.—It is true.

Q.—You paid for it and put it in the paper? A.—Yes.

Mr. Brown:—Mark that for identification.

Whereupon, said instrument was marked Exhibit D-10 for identification.

Q.—We hand you what is originally marked Defendant's Exhibit No. 26, for identification, M. M. F. 3/8/39, with your name on it and I will ask if that was your advertisement? A.—This is a copy of a letter I received from S. I. DeLoach.

Q.—You had that inserted in the paper did you not? A.—Yes.

Q.—And paid for it? A.—I did.

Mr. Brown:—We mark this for identification and reserve our rights.

Advertisement was then marked for identification as Exhibit "D-11."

Q.—Here is what purports to be an ad from the El Paso Times of October 25th, 1931, and I will ask you to identify that, Doctor, and state whether or not it is your advertisement? A.—It is.

Q.—You had it made and paid for it? A.—It is a good one and an honest one.

Q.—Who put it out? A.—I did.

Q.—Paid for it? A.—I did.

Q.—Who prepared it? A.—I don't know.

Mr. Brown:—We have that marked for identification as Exhibit 12.

Advertisement was then marked for identification as Exhibit "D-12."

Q.—You had a half dozen different people preparing these ads at times? A.—At different times.

Q.—Here is something taken from the El Paso Times of June 19th, 1921. A.—This was a news item.

Q.—You saw it and have read it? A.—I have.

Q.—And read it at the time? A.—I read it at the time.

Q.—And the information in this news article came from you did it not? A.—No, it came from Mr. Griffin, the gentleman I was treating. He was in the office every day.

Q.—How did he get the names mentioned in this article? A.—He knew most of them.

Q.—The people from Pine Bluff? A.—I gave him the names from Pine Bluff.

Q.—You furnished the information that formed the basis of this article? A.—He got the basis of that from patients he met in the office when I was treating him.

Q.—You did not see fit to correct anything in that article? A.—I told him there were things to be corrected, he said he was responsible for it himself, it was a news item and it did not need to be corrected.

Q.—You let it stand without contradiction and without question? A.—Yes.

Mr. Brown:—We will have that marked for identification as Exhibit 13.

Advertisement was then marked for identification as Exhibit "D-13."

Q.—I show you what appears to be a full page ad or approximately so from the El Paso Times, Sunday, August 10th, 1924. Did you ever see that? A.—Yes, I have seen this.

Q.—That is your advertisement is it not? A.—Yes.

Q.—You had it put in the paper? A.—I did and paid for it.

Q.—And you compiled the data? A.—I did.

Q.—It is marked originally "Defendant's Exhibit 22, for identification, M. M. F. 3/8/29." You put that in the paper? A.—I did.

Mr. Brown:—We have this marked Exhibit 14 for identification.

Advertisement was then marked for identification as Exhibit "D-14."

Mr. Brown:—We reserve our rights on that.

Q.—Now, didn't you, Dr. Brunson, over a period of considerable time have daily ads inserted, advertisements inserted in the El Paso papers? A.—I did for a while.

Q.—For how long a period of time? A.—I do not know exactly. It has been six years since I advertised at all.

Q.—But you did for a period of five or six years run daily advertisements in the paper? A.—I did. I wouldn't say daily. I ran them possibly twice a week.

Q.—Generally you would have them in the Sunday issue would you not? A.—What?

Q.—In the Sunday issues particularly? A.—Yes.

Q.—Sometimes full page ads? A.—I have had full page ads.

Q.—Did you have anybody employed as a publicity agent? A.—No.

Q.—But you did have somebody employed for the purpose of aiding you in preparing and compiling these ads? A.—Most of the time it was done by the advertising manager of the paper.

Q.—Part of the time though you had somebody paid and employed for that purpose? A.—Yes, for part of the time.

ARCHIVES OF SURGERY: NEW EDITORIAL DEVELOPMENTS

Development of surgery in the United States has been unprecedented for its rapidity, its quality and its scientific character. Few, if any, would contest the claim that today American surgery leads all the world. In 1920, when the *Archives of Surgery* was established by the American Medical Association, there were but two important periodicals in the surgical field in this country. The space available was hardly sufficient for the publication of all contributions of value—seldom was it possible to publish articles of more than eight or ten pages. These restrictions prevented the publication of many important surgical contributions, especially in the field of experimental surgery. It is not surprising, therefore, that the *Archives of Surgery* has become in the intervening years the leading publication in the field of experimental surgery and that references to articles published in its pages constitute a large part of the bibliographies of articles on surgical subjects published in foreign periodicals. In every survey of bibliographic references that has been made, references to the *Archives* indicate that it has been the leading source of consultation in the last two decades.

The highly technical character of much of the material that has appeared in the *Archives of Surgery* has tended to divert attention to some extent from the *Archives* to other surgical publications, which have stressed more particularly contributions in the field of clinical surgery and articles dealing with modifications in surgical technique. The unfortunate illness of Dr. Dean Lewis, Editor in Chief of the *Archives of Surgery* since it was established, brought to the attention of the Board of Trustees of the American Medical Association some of these special problems associated with this publication.

After much consideration it was determined to expand the editorial board of the *Archives* and to modify the nature of the contents of the periodical in order to make it fulfil more completely its original purpose. Four additional members have now been added to the Editorial Board: Dr. Arthur W. Allen, Boston; Dr. Alfred Blalock, Nashville, Tenn.; Dr. W. E. Dandy, Baltimore,

and Dr. L. R. Dragstedt, Chicago. Dr. Waltman Walters has been made chairman pro tem., during the incapacity of Dr. Lewis. It has been decided to publish papers dealing with clinical investigation on surgical problems as well as articles which concern developments in the various special fields of general surgery. Collective reviews will be published from time to time, written by competent investigators who have devoted themselves particularly to special subjects and who will be invited by the editors to develop such reviews. The *Archives* will provide prompt publication each month of short preliminary reports of noteworthy surgical advances made by its contributors.

These decisions have been reached after careful consideration of the problems in conferences of the Editorial Board and of members of the Editorial Board with the Board of Trustees. It is anticipated that the surgeons of the United States will welcome the opportunity for more prompt publication in the field of surgery and the availability of the *Archives* as an authoritative medium for the recording of surgical advancement.

THE PATHOLOGY OF OBSTETRIC SHOCK

Although the term "obstetric shock" may be variously interpreted, it seems to be without exact definition. Clinically the concept of "pure obstetric shock" excludes all cases in which the etiologic factor is known. Pathologically the essential requirement is that the patient shall have died of shock in connection with obstetrics. Postmortem investigation frequently discloses gross lesions which had not been suspected clinically and furnishes moreover a few possible clues as to the mechanism of shock. It does not explain, however, how inversion of the uterus, for example, can produce the functional disturbance known as shock.

In a study of the pathologic anatomy of obstetric shock, Sheehan¹ reviewed all the fatal cases of obstetric shock seen in the Glasgow Maternity Hospital during the previous five and one-half years. The criterion of obstetric shock that was adopted is wider than that in common clinical use; that is, if the patient with the clinical appearances of shock died during labor or within twenty-four hours after delivery, whether or not any explanation for the shock had been recognized before death. The cases finally selected were grouped according to the apparent etiologic factors: dystocia twenty-nine cases, ruptured uterus thirteen cases, retained placenta twenty-two cases, uteroplacental apoplexy twenty-one cases, uncomplicated cesarean section four cases, and complicating disease eight cases. The cause of dystocia was simple disproportion, occipitoposterior presentation or, more rarely, hydrocephalus or oblique intra-uterine position. The second group, in which ruptured uterus was regarded as the cause of death, was closely related with the previous group. Seven of these patients had dystocia requiring intra-uterine

1. Sheehan, H. L.: The Pathology of Obstetric Shock, *J. Obst. & Gynec. Brit. Emp.* 46: 218 (April) 1939.

manipulations; the other six patients had spontaneous ruptures. The retained placenta group could be divided into six patients who died between two and three hours after delivery and sixteen patients, of whom eleven died between four and eight hours after delivery and the other five between eight and twenty-four hours after delivery. The twenty-one cases in the uteroplacental apoplexy group were so called as representing mixed or concealed accidental hemorrhage with retroplacental clot. Although these cases are usually classified under the heading "hemorrhage," the usual cause of death is shock. Of the eight cases due to complicating disease, death occurred in one before delivery and in the others within eight hours after delivery. Four of the patients had definite evidence of previous hypertension; the others had lobar pneumonia, acute hemorrhagic pancreatitis, renal disease and influenza respectively.

The principal characteristic demonstrable organic pathologic changes given by Sheehan consisted of the presence of subendocardial hemorrhages on the left of the interventricular septum, a uterine appearance dependent on the clinical condition, occasional hemorrhages into the ovaries, edema of the parametrium and pelvic tissues in some instances, acute dilatation of the stomach with air, commonly, and necrosis of the anterior lobe of the pituitary gland, if the patient who died of obstetric shock survived for a day or more. Such a variety of pathologic manifestations may well be difficult to include as a concrete syndrome.

THE FUNCTION OF THE STATE IN MEDICINE

In a meeting of the Section of Epidemiology and State Medicine of the Royal Society of Medicine in Great Britain a symposium was held during February 1939 on the proper sphere of state medicine. In the opening statement, by Dr. Alfred Cox, former secretary of the British Medical Association, he pointed out that even with all his experience in this matter he was unable to accept the solution that the state should make medicine free to all. Some of his statements merit particular quotation; thus Dr. Cox said:

In a world which is becoming more and more machine made and mechanized, in which the individual tends to become more and more swamped in the mass, it seems to me a good thing, indeed an imperative duty, whenever we can, to keep our profession, and the rights and privileges and welfare of the individual, free from the shackles of standardization—a condition which is the inevitable result of government control. Nowhere is such an effort so necessary as in those countries which profess to believe in freedom of thought and action, and dislike the growth of the authoritarian idea.

In his concluding remarks, he said:

As at present advised, therefore, the answer I give to the question in debate is this: The proper function of the state, so far as the actual provision of medical attendance is concerned, is to leave it as far as possible to a free profession dealing with a free people; to encourage the profession and people to make voluntary arrangements where practicable, preferably on an insurance basis; to make such arrangements compulsory

where the voluntary principle does not work; to aid financially those citizens who cannot provide entirely for themselves; and to keep the "dead hand" of officialdom as far off as possible. I want to make progress without impairing some of the most precious gifts possessed by the ordinary man, namely the desire to help himself, to be independent and to be regarded not as a mere cog in the state machine but as a self-respecting and, so far as possible, a self-maintaining citizen. In this way of approach I believe we shall not only be doing the best we can for our potential patients and for our profession—which can only operate to its maximum capacity as a *free* profession—but also for the community as a whole, by making it clear that in the field of medicine we desire to minimize state control because it is likely to officialize our profession and consequently lessen its usefulness to the individuals who form the community.

Dr. Andrew Topping emphasized that the demands for the services of the general practitioner are becoming less and less in Great Britain. He satirized the concentration of specialists in the Harley Street area and said that, since the crux of the whole situation is financial, state medical service should be the aim. He emphasized, however, that control of the service must be entirely nonpolitical and must be in the hands of medical men recruited from all branches of the profession.

Dr. Frank Gray pointed to the salaried medical service of the London County Council as being a fine example of the possibility of administering service with a salaried profession but said also that unfortunately there are other salaried services besides those of the London County Council which were apparently not nearly so satisfactory. The essential feature of such a service is the salary and consequent security, but with that is a contentment which brings rigidity and inertia. "It is a remarkable fact," he said, "that though we have had National Health Insurance for over twenty-five years, and a Ministry of Health for twenty, the only postgraduate instruction in preventive medicine for general practitioners has been organized by two groups of London doctors, and not by the ministry." He pointed out that, further, "Nothing is done without stirring up trouble, and the chief object of a government servant is to avoid stirring up trouble."

Statements by Dr. E. R. C. Walker and Mr. Somerville Hastings indicated still further that Great Britain has not yet found a satisfactory answer for its medical problem.

Dr. F. C. White concluded the discussion by pointing out that neither the state nor the municipality ever took over a service which was being efficiently provided by private enterprise. He felt that state medical service in Great Britain is inevitable but that at the same time the ideal should be "to ensure that every case of illness is seen in the first instance in the patient's own home by his own family doctor."

The more one reads of these discussions by medical men in various foreign countries, the more is one convinced that they are still experimenting, still blundering, still trying to evolve a wide distribution of high quality of medical service, without having achieved in any country much better distribution of high quality of medical service than is available in the United States today.

INFLUENCE OF THYROID THERAPY ON MENTAL GROWTH OF CRETINS

Only by careful studies of the detailed investigations of the physiologic effects of thyroid therapy can maximum assistance be given to those unfortunate children who suffer from cretinism or juvenile hypothyroidism. Although some of those afflicted with cretinism respond poorly to treatment even when it is given promptly, the value of early diagnosis and treatment of this condition is shown by numerous observations. In a recent report, Brown and his co-workers¹ describe the influence of thyroid therapy on the mental growth of children suffering from cretinism. The record covers a carefully carried out investigation of the degree of mental development of these patients during treatment, as determined by psychologic tests given over a period of from one to seven years. Like other investigators, Brown and his collaborators observed that even with treatment most of the children remained severely retarded mentally. Despite thyroid therapy for from one to seven years, in about 75 per cent of the twenty-nine cases studied the intelligence quotient was below 80, in 25 per cent below 45 (at the imbecile level or below) while in only two cases was the quotient above 100. In both of the latter cases the treatment suggested that the best results in this direction are obtained when an early diagnosis is made and when treatment thereafter is persistent and active. Throughout the group there was a slight increase in the intelligence quotient during the period of treatment of the patients studied; moreover, the increase was greatest for those whose treatment was begun early. Although 25 per cent of the patients were at the imbecile level and 50 per cent at the borderline or high grade defective level in spite of persistent and active treatment, it should be recognized, as pointed out by Brown and his associates, that without treatment all of them would probably be at the imbecile or idiot level.

In a study of the value of thyroid therapy on a large number of cretins, Lewis² observed that, in the majority of his patients, there was a rough correspondence between adequacy of treatment and the intellectual level attained but that it was possible for some cretins to reach a normal mental level. Promptness and continuity of the administration of thyroid are, however, apparently not the only decisive factors in determining to what extent the cretinous child will remain backward. Other factors, such as the stage of development at which symptoms of thyroid deficiency appeared, the degree of this deficiency, the hereditary endowment of the child and any cerebral damage either at birth or in infancy, have been stated to influence psychologic attainment. Similar factors have been emphasized in a report by

Gesell and his co-workers.³ Thus, the available evidence indicates that, although the level of mentality of cretins can rarely be brought within the normal range by thyroid treatment, there is in many cases a favorable response which shows a rough correlation to the intensity of treatment.

Current Comment

FOURTH OF JULY INJURIES

For the past two years the American Medical Association has resumed its annual summaries of the injuries from fireworks resulting from the celebration of the Fourth of July. In 1938, eighteen deaths were directly attributable to fireworks and seven were indirectly due to the same cause. Two cases of tetanus were reported in 1938, as in the previous year. Last year there were 7,933 injuries recorded, as compared with 7,205 in the preceding year. Since last year a few of the states with the worst records of deaths and injuries from fireworks have enacted legislation aimed at the prevention of this unnecessary source of danger. Again the cooperation of hospitals throughout the country has been requested to assist in carrying to the public consciousness the unnecessary hazard of allowing fireworks to be sold indiscriminately to the public.

INFECTIOUS MONONUCLEOSIS

The diagnosis of infectious mononucleosis is often difficult. Thus Marshall¹ recently reported four cases of infectious mononucleosis, each simulating a different disease. In one case the dominating symptoms were cerebral, one simulated lymphatic leukemia, one presented all the appearances of follicular tonsillitis and in one weakness was the principal symptom. These cases clearly demonstrate the practical value of the specific heterophile antibody test stemming from the early work of Forssman. In fact the correct diagnosis probably would have been missed without the help of this diagnostic procedure. Saphir² has reported a case of infectious mononucleosis in which the clinical picture was similar to preeruptive and later to secondary syphilis. In this case four plus Wassermann and Kahn reactions and a papular rash increased the diagnostic difficulties. As Saphir pointed out, had the heterophilic antibody test not been performed and the characteristic reaction noted, the case would doubtless have been diagnosed as one of preeruptive syphilis. The subsequent disappearance of the positive Wassermann reaction would then have been attributed to the antisyphilitic treatment. The serologic problems raised by the presence of the heterophile antibody reaction and the positive Wassermann test cannot however be satisfactorily explained at present. Certainly the bizarre symptomatology of infectious mononucleosis calls for a specific diagnostic procedure which the heterophile antibody test appears to fulfil.

ORGANIZATION SECTION

HEALTH PROBLEMS IN EDUCATION

THIRD SYMPOSIUM, HELD AT ST. LOUIS, MAY 16, 1939

DR. S. JUDD BEACH, PORTLAND, MAINE, IN THE CHAIR

A Symposium on Health Problems in Education was arranged by the Joint Committee on Health Problems in Education of the National Education Association and the American Medical Association to be held during the annual session of the American Medical Association at St. Louis. Joint sponsors were the Section on Ophthalmology, the Section on Pediatrics, the Section on Preventive and Industrial Medicine and Public Health, and the Section on Laryngology, Otolaryngology and Rhinology of the American Medical Association. The date of the Symposium was May 16. Dr. S. Judd Beach, chairman of the Section on Ophthalmology, presided.

All the speakers were furnished a copy of a tentative statement of health policies recommended for school health work, prepared by the Child Health Section of the American Public Health Association and a committee of the American Academy of Pediatrics. This statement is not available for publication in full because it remains in tentative form at this time. The most important principles advocated in the tentative statement are as follows:

RESPONSIBILITIES OF SCHOOL HEALTH PROGRAMS

1. To provide a healthful environment. This includes attention to the arrangement of the school program and the social and emotional tone of the classroom as well as attention to school sanitation.
2. To have a planned program for the care of accidents occurring at school and for cases of sudden sickness.
3. To have a planned program for assisting in the community program of contagious disease control.
4. To teach pupils habits and attitudes conducive to the maintenance of good health, and to facilitate the accumulation of scientific knowledge relating to the causes of disease, the way certain diseases are spread, and the known methods of preventing disease from the point of view of both individual and community health.
5. To encourage the periodic health examinations of pupils, to develop a plan whereby such examinations will be obtained, and to keep a cumulative record of the findings and recommendations.
6. To give special attention to those in need of medical or dental care through a follow-up program which will, where necessary, guide pupils and parents to sources of medical and dental treatment.
7. To provide special education programs adapted to the needs of handicapped pupils.
8. To provide supervision and in-service training for teachers and to place specific responsibility in the hands of some person especially qualified in education and in school health work for coordinating all school health activities and for relating these to community health programs.

Following are abstracts of the papers presented in the symposium. Mimeographed copies of the complete papers are available and may be obtained from the Bureau of Health Education of the American Medical Association.

SCHOOL HEALTH PROBLEMS

I. From the Point of View of a School Physician

J. H. HUMPHREY, M.D.

Director of Hygiene, St. Louis Public Schools, Board of Education
St. Louis

The health program in the St. Louis public schools is divided into three phases: health service, health education and physical education. It is the responsibility of the school authorities to insure the best possible hygienic surroundings for the child while he is in school.

The first consideration in a health service program is an adequate personnel of qualified physicians and nurses. Our program begins before the child enters kindergarten and is carried on until he leaves high school. For the past twelve years we have conducted annual physical examinations of the preschool child. The parent is invited to be present and is shown the existence of any defects and the importance of having them corrected. Many schools have reported 100 per cent parent attendance. All children entering school for the first time who have not had a preschool examination are given the same type of examination, the parent or legal guardian being present.

Physical examinations are conducted every three years during elementary school life and more often, if necessary. Students entering high school and those in the senior year are given a careful examination. Children returning from absences because of serious illness are examined by the school physician. When a child is found to have a physical defect which requires correction, the physician notifies the parent or legal guardian, recommending that the child be taken to the family physician or dentist for advice or treatment.

The school physician also makes examinations to determine physical eligibility for assignment to various special schools and classes for the physically handicapped; to determine physical fitness of pupils desiring to participate in athletics; of pupils seeking work permits; of teachers after leave of absence; of applicants for certain positions in the instruction department; of food handlers in the lunchrooms; of Girl and Boy Scouts, for swimming and other activities; and of students in vocational schools, to guide them into trades and occupations for which they are best fitted physically.

In pursuing the policy of having parents responsible, the nurse visits the home or invites the parent to the school. This brings closer cooperation between home and school. It is the policy of the St. Louis public school system to seek correction of physical defects through the family physician or by means of clinics.

A health record card is kept for each child. These records follow the child from the prekindergarten examination through high school. In addition, all outstanding defects which might interfere with the child's progress in school are recorded on the teacher's cumulative card.

Defective vision and hearing are probably the most important physical defects in relation to school retardation. Audiometer tests have been conducted for the past twelve years by a school nurse. Individual graphic weight charts are kept and the child who fails to gain, or is losing in weight, over a period of three consecutive months is referred by the school nurse to the school physician for examination. A conference is arranged with the parent in order that the cause may be determined, if possible.

Medical care, except for emergency first aid, is not the responsibility of school authorities but is the proper function of the home, in cooperation with the family physician. The school physician acts only in an advisory capacity by informing the parent of physical defects or other conditions which might require medical care.

The goal for which we should strive is a physical examination for each child at regular intervals during his school life, such examinations to be given preferably by the private physician. However, there will be a large number who cannot or will not go to a private physician and it will then be necessary that these examinations be conducted by the school physician in order that our health program be effective.

II. From the Point of View of a Physical Educator

N. P. NEILSON, PH.D.

Executive Secretary, American Association for Health, Physical Education and Recreation, a Department of the National Education Association
WASHINGTON, D. C.

In dealing with children, parents have always exercised and will continue to exercise certain functions which may be classified as educative and protective. Health protection and health instruction procedures were gradually developed and these together become known as the school health program. Health service and health supervision are a part of this program.

Competent physical educators recognize that the school should assume definite responsibilities or functions in the field of health. These functions include health instruction which implies acquisition of knowledge, development of attitudes, and formation of habits or ways of acting; maintenance of a healthful environment; daily observation and inspection for the control of communicable diseases; insistence on health examinations performed in school or away from school for the discovery of defects which impair health or adversely affect school progress; follow-up service to secure the correction of remedial defects; the hygiene of instruction; prevention and emergency care of injuries; and, in general, adaptation of the school program to the health needs of each individual pupil. In performing these functions the school may do more than help the child maintain his present state of health. However, it is not to be assumed that the school is responsible for the child's total health problem.

The criteria of a satisfactory physical education program, applicable to both elementary and secondary schools, are: (1) a daily program for all pupils enrolled in school; (2) a natural game type of program rather than formal exercises invented by adults for adults; (3) use of a great variety of activities suited to pupils of various age levels; (4) discovery of the needs of pupils through tests and examinations conducted by the physician and the physical education teacher; (5) adaptation of the program to the needs of each pupil; (6) adequate indoor and outdoor equipment and facilities, and (7) well qualified teachers.

The physical educator should know the needs of people and values of activities so he can deliberately adjust or adapt the program to the needs of each individual. The physical educator must have a thorough grounding in the biologic, physical and social sciences. To discover pupil needs, the physical educator should be prepared to make inspections and to give tests and examinations up to the point of a differential diagnosis of pathologic conditions. Up to this point these are his functions as an educator. Beyond this point he must not go but must rely on the services of a physician or of other health service personnel. It is not correct to say "the health of children is in the hands of physicians or of teachers or of the home." Parents, teachers, physicians, nurses, boards of public health and welfare agencies are health experts in different fields and all should work together on a balanced health program.

There is a special need for cooperation of the physician and the physical education teacher. Neither worker has known enough about their mutual problems. The physical educator must have an understanding and just evaluation of the resources of modern medical science and practice.

Physicians need to know more about normal child development and about schools. Physicians generally do not know enough about the hygienic, developmental and corrective values of physical education activities. There is a sincere desire on the part of competent physical education teachers to discuss health problems with school and family physicians and to secure sound advice so that the physical education program may be adapted to pupil needs. Special cooperation is required in the corrective program and in the interscholastic program of athletics for boys.

There is a body of health knowledge and a series of health practices which may be logically and best taught in connection with physical education activities. The physical education teacher should not fail to perform these functions. Similarly biology, science and home economics teachers have health teaching responsibilities. The health instruction which cannot be associated with other activities can best be taught in a separate course, with the problem approach, and by a teacher specially prepared.

III. From the Point of View of a Practicing Physician

WINGATE M. JOHNSON, M.D.

WINSTON-SALEM, NORTH CAROLINA

After carefully reading and rereading the tentative statement of school health policies prepared by the Child Health Section of the American Public Health Association and the committee of the American Academy of Pediatrics, I was quite disappointed. There was almost nothing with which to disagree. Under the circumstances, however, I shall do my best to find some bits to object to, possibly a suggestion or two to offer, and—a much more pleasant task—to agree with as much of the document as time permits.

My first mild objection is to the paragraph stating "The mental health of pupils requires that teaching methods shall give ample opportunity for experiencing success, that disciplinary measures consider pupil personality of greater importance than the rigid application of arbitrary rules and that types of examinations and methods of promotion do not result in discouraging or degrading experiences." While no child should be made to suffer unnecessary humiliation, is there not danger, in trying to save a child momentary embarrassment, of sending him out into the world totally unprepared for the cruel bludgeonings of fate that must inevitably be suffered? To leave the impression on the school child that only rewards are to be expected is mistaken kindness. In the laudable effort to spare "discouraging experiences" there is a widespread tendency to discard such difficult subjects as Latin, Greek and mathematics in favor of the earlier vocational classes, thus depriving the student of an opportunity to develop his mental muscles.

The importance of careful physical examinations preliminary to entering school, and at intervals during school years, can hardly be questioned. Height and weight tables, however, should not be taken too seriously. They represent only the average and make no allowance for individual variation. The laws of heredity should not be forgotten.

A misconception resulting from emphasis placed on defects found in routine examinations is the popular idea that physical faults are always responsible for low IQ's and that their correction will automatically insure a first-class set of brains. Only too often, however, the attempt to take a child out of the repeater class by removing his tonsils and adenoids or straightening his teeth is a praiseworthy but futile effort to thwart the will of the Almighty.

The family doctor should be willing and even eager to cooperate with the school authorities, the school physician and the health department in examining school children, in the control of communicable diseases and in health education. In return, he should be recognized by having children of his families referred to him for preschool and school examinations and for the necessary medical services needed in school examinations and for the necessary medical services needed in school beyond the simple emergencies which the school nurse, athletic instructor or teacher is capable of handling. A simple form of exam-

ination card should be issued to parents with the request that the children be carried to the family doctor for examination.

I agree heartily with the suggestion that the name and address of each pupil's private physician and dentist be kept as part of the school record. With the paragraph scoring "false emphasis on perfect attendance" I should like fairly to shout my agreement. For many years I have advised the mothers of children under my care to keep their children at home the second day of every school year, so there would be no perfect attendance record to maintain.

The school day for the children in the first three grades should be materially shorter than for the older ones. In the agitation for shorter working days for adults, it is to be hoped that the little folks may be remembered also.

IV. From the Point of View of a School Administrator

HENRY J. GERLING

Superintendent of Instruction, Board of Education,
of the City of St. Louis
St. Louis

The development of a health program is a problem of public opinion. It must have the support and confidence of the public. An important aspect is the problem of financial support. It has always been difficult to develop new auxiliary service, however important, at the expense of direct instruction in the school curriculum. The money coming to a school system for its support is limited by law. Every expenditure for auxiliary service reduces the potential fund available for direct teaching.

Among the important features added to the health program of the public school system in St. Louis during the past seventeen years without increasing the rate of school tax, and maintained throughout the economic depression when the total revenue was reduced more than 30 per cent, are included the following:

1. Health teaching as a part of the school curriculum and specialized supervision of the health instruction program.
2. Increase of the number of school physicians and school nurses from fifteen physicians and twenty-seven nurses in 1922, to eighteen full-time and three part-time physicians and forty-three nurses in 1939.
3. Instruction in the use of the audiometer to detect defective hearing.
4. Establishment of schools for crippled children, with bus transportation from every part of the city.
5. Establishment of sight conservation classes.
6. Numerous improvements in the construction and equipment of buildings for the purpose of protecting and promoting health.

Further development of the health program awaits the willingness of the public to raise its legal limit of tax rate in order to provide the necessary funds to support a health program as a necessary and integral part of the schools' function.

Two other recognized responsibilities of the public schools closely related to health are the safety program and the system of summer playgrounds.

The St. Louis Board of Education provides in many ways for children handicapped by health or physical defect. There are sight conservation classes and special attention to speech correction, the deaf and the hard of hearing. There are open air classes and a school for crippled children where two thirds of the children are at present on the schedule for corrective exercises. There is a school for care of Negro pupils who are crippled, deaf, hard of hearing, anemic or in need of special work for sight conservation.

Systematic inspection for contagious diseases has been established in the schools, and the spread of these diseases has since been kept to a minimum. Preschool examinations constitute the latest innovation in promoting school health.

The future of a school health program depends on continued support of public opinion and the willingness of the public to increase the revenues needed for the support of public education on a basis that promotes the ancient but persistent idea of a sound mind in a sound body.

THE TUBERCULOSIS PROBLEM IN THE SCHOOLS

CAMILLE KERESZTURI, M.D.
NEW YORK

Like any other health program, tuberculosis work in schools should start with the education of parents, pupils and teachers. Preventive efforts and their significance should be understood in order to obtain active cooperation. Medical knowledge must be dispensed with application of appropriate psychologic skill so that health consciousness is acquired without nosophobia or hypochondria.

After the education of parents, teachers and pupils is accomplished and their cooperation is obtained, and only then should the actual health program proceed.

Tuberculosis surveys should be done systematically every year.

A simple, inexpensive and effective procedure includes:

1. Tuberculin tests at the beginning of the school term.
2. Chest roentgenograms on all positive reactors.
3. Physical examination; sedimentation rates; sputum examination of pupils whose chest roentgenograms show lesions suggestive of fresh or active tuberculosis.
4. Retesting of all negative reactors six months later.
5. X-ray examination of all positive reactors yearly.

THE STATUS OF HEALTH EDUCATION IN THE SCHOOLS

LLOYD W. KING

Superintendent, Department of Public Schools, State of Missouri
JEFFERSON CITY, MO.

The supervisor of health education of the Missouri state department of education devotes full time to coordinating, promoting and supervising the public school health program.

The school should provide a happy, safe and healthful environment for the child. The physical condition of the schools will be reflected for years to come in improved health of school children. The construction and remodeling of all school buildings seeks to comply with two main objectives: (1) the protection of life; (2) the protection of health.

The public schools have shared substantially in the fast-growing public health program in Missouri. The majority of county nursing services established in the past year are supported in part by public school funds. Teachers are trained to look for deviations from the normal and insist on examination and correction by the family physician. School health demonstrations, designed to show teachers how they may carry on health programs even with limited facilities, cover these fundamentals: morning inspection; vision and hearing tests; handwashing; hot lunch; weighing and measuring; birth registration; first aid.

Providing for the integration of related subjects into large fields, health finds its logical place in the science and the recreation arts area. This arrangement tends to break down the numerous departments of subject matter and permits integration on a functional basis.

Teacher training institutions are setting the pace for health education in our public schools. The state teachers' colleges and the state university are giving increased attention to the health of their students.

Health education in Missouri, as in many states, is just now finding itself in the complete program of education. We are encouraged by the interest of the teachers in doing a better job of teaching health; by the current building and remodeling program providing for environment favorable to health; by the increase in public health service in our state; by the enthusiasm with which our school people have accepted the new courses of study, and by the trend toward improved teacher training facilities. On these foundations it is hoped to build a permanent school health program that will be reflected forever in the improved physical, mental and social health of school children.

COMMUNITY PARTICIPATION IN A HEALTH PROGRAM

THEODORE R. MEYER, M.D., DR.P.H.

Deputy State Health Commissioner, St. Louis County Health Department
CLAYTON, MO.

The public health official of today must have as a part of his armamentarium a well organized program of health education in which the family physician, the layman and the health commissioner must participate. The educative approach of a modern health department is in marked contrast to the methods of force used in the days of the earliest health departments.

The rate of progress of public health work is determined by public acceptance. The objectives, aims and methods of a department of health are less understood by the public than any other branch of state or municipal government and in many respects this fault is often that of the department of health and its personnel.

Human relationship is the fundamental basis of successful public health work. The impression that the health department makes on the public definitely determines whether its work will continue to gain popular support. The people must be familiarized with the values of a health department and what it means to them in their daily routine of living.

In St. Louis County we have incorporated into our program a plan and philosophy of utilizing every community facility that is available. Minimizing the introduction or importation of foreign personnel has a definite bearing on the community interest. Political organizations have been sold on the fact that health department personnel must be employed on the basis of training and qualifications and not because they are sponsored by a political organization. Cooperation from the public officials in our area has made this possible. They realize that the health and welfare of their citizens is far above filling these positions as a political reward.

The department has been cautious in the selection of the nursing personnel, since these individuals represent the department of health in the most intimate relationship with the public.

Public health is an outgrowth of medical practice and it was deemed advisable to place the reorganized county health department in the St. Louis County Hospital and in this way the department took on an atmosphere of a health center. The county officials are exerting every possible effort to make available a properly constructed and adequately equipped building. This health center, in its future plan, recognizes the important role of the family physician and will have provisions for meeting places for the medical society, in order that it may be definitely identified with the department of health activities.

Another avenue of stimulating community interest and participation has been through the cooperation of the social planning council. Last year, as a stimulator of community interest, we thought it advisable in two school districts, which could raise the funds on a matched basis with the state board of health, to provide public health nurses limited to the communities participating. The purpose was to institute a program dealing with all the ramifications of public health, centered around the school in such a small area that it would reach every one. The program has been effectual and has induced other areas to solicit similar programs voluntarily.

The health department cooperates definitely with the St. Louis County Medical Society, and the society has representation and a voice in the policies of our program.

The two salient features of our medical examination program are: (1) transfer examinations of school children from the schools to the family physician's office; (2) change of the term "physical" examination to "medical examination." Through cooperation of the county medical society, 142 physicians have gone on record agreeing to make medical examinations of school children in their offices at designated hours without cost. The program also cooperates with the physician in maternal welfare, venereal disease, tuberculosis and rabies programs, and communicable disease control.

The organized medical profession can make a material contribution to the improvement of public health. Our program of medical participation in health work is profitable to the physician, the health department and the public.

OFFICIAL NOTES

ADDRESSES BY OFFICIAL STAFF

DR. W. W. BAUER:

- July 4—National Education Association, Annual Convention, Executive Committee, San Francisco.
- July 5—National Education Association, Annual Convention, Representative Assembly and the Symposium on School Health, San Francisco.
- July 6—National Education Association, Annual Convention, Conference of Joint Committee on Health Problems in Education, San Francisco.

DR. MORRIS FISHBEIN:

July 12—Miami University, Oxford, Ohio.

DR. R. G. LELAND:

July 19—Tennessee Pharmaceutical Association, Memphis, Tenn.

MR. A. M. SIMONS:

July 16—Economics Committee, American Dental Association, Milwaukee.

MEDICAL LEGISLATION

MEDICAL BILLS IN CONGRESS

Changes in Status.—Senator Sheppard, Texas, has proposed an amendment to H. R. 5452, now pending in the Senate Committee on Finance, providing that, in the administration laws pertaining to veterans, retired enlisted men of the Army, Navy, Marine Corps and Coast Guard who served during a war period as recognized by the Veterans' Administration and who have been honorably discharged from such service, shall be entitled to hospitalization and domiciliary care in Veterans' Administration facilities on parity with other war veterans. Senator Reynolds, North Carolina, has submitted a proposed amendment to S. 2304, now pending in the Senate Committee on Military Affairs, to provide hospitalization for certain persons who have served in the Coast Guard. Senator George, Georgia, has submitted a proposed amendment to H. R. 6635, now pending in the Senate Committee on Finance, to increase from \$8,000,000

to \$12,000,000 the annual federal appropriation under the Social Security Act to assist states, counties, health districts and other political subdivisions of the states in establishing and maintaining adequate public health services including the training of personnel for state and local health work. Senator Wagner, New York, has submitted a proposed amendment to the same bill, H. R. 6635, that proposes, among other things, to add a new section to the Social Security Act under which to pay disability benefits to certain persons totally and permanently unable to work by reason of illness or injury not arising out of or in the course of employment and to authorize the Social Security Board to provide for the furnishing of medical, surgical, institutional, rehabilitation or other services to individuals entitled to such disability benefits, such services to be furnished by qualified practitioners and by governmental and nongovernmental hospitals and other institutions qualified to furnish such service. H. R. 5762 has been signed by the President, provid-

ing for the temporary postponement of the operations of certain provisions of the Federal Food, Drug and Cosmetic Act. H. R. 6076 has passed the House and has been reported to the Senate, with recommendation that it pass, providing for the registry of pursers and surgeons as staff officers on vessels of the United States.

Bills Introduced.—H. R. 6450, introduced by Representative Voorhis, California, provides that wherever a veteran seeking service connection is shown to have been engaged in combat with the enemy or to have been subjected to other conditions within the zone of advance which can, in good medical judgment, be considered as causing or aggravating the disability or disabilities on which the veteran's claim is based, then the disability or disabilities shall be considered to have been caused or aggravated by military service. H. R. 6652, introduced by Representative Boren, Oklahoma, proposes to authorize the Secretary of Commerce, through the National Bureau of Standards, to establish and publish standards of quality for consumer goods, excepting foods, drugs, cosmetics and other articles for which federal standards are now provided by law, when in his

judgment such standards are in the public interest. H. R. 6800, introduced by Representative Zimmerman, Missouri, proposes, among other things, that the same privilege of hospitalization and medical care and treatment accorded to honorably discharged veterans of the Spanish-American War, the Philippine Insurrection, the Boxer Rebellion and the World War shall be extended to honorably discharged veterans of the Moro and Pulajane wars or campaigns, or other campaigns which took place in the Philippine Islands between the dates of July 5, 1902, and Aug. 5, 1913, inclusive.

DISTRICT OF COLUMBIA

Changes in Status.—S. 1805 has been reported to the House with recommendation that it pass, proposing to establish a lien for moneys due hospitals for services rendered in cases caused by negligence or fault of others. H. R. 5238, proposing to regulate the practice of optometry in the District of Columbia, has been reported to the House with recommendation that it pass.

WOMAN'S AUXILIARY

OFFICERS OF THE WOMAN'S AUXILIARY FOR 1939-1940

The following officers have been elected by the Woman's Auxiliary to the American Medical Association for 1939-1940:

President—Mrs. Rollo K. Packard, 6901 Paxton Avenue, Chicago.
President-Elect—Mrs. V. E. Holcombe, 1635 Quarrier Street, Charleston, W. Va.
First Vice President—Mrs. David W. Thomas, 112 West Main Street, Lock Haven, Pa.
Second Vice President—Mrs. Otto C. Hagmeier, 1025 South Prom, Seaside, Ore.
Third Vice President—Mrs. M. B. Van Cleave, 505 South Fourth Street, Terre Haute, Ind.
Fourth Vice President—Mrs. W. K. West, 233 Northwest Thirty-Third Street, Oklahoma City.
Treasurer—Mrs. E. E. Fisher, Multnomah County Hospital, Portland, Ore.
Recording Secretary—Mrs. John L. Bauer, 984 Bushwick Avenue, Brooklyn.
Corresponding Secretary—Mrs. Lucius Cole, 1117 Lathrop Avenue, River Forest, Ill.
Directors, one year—Mrs. Charles C. Tomlinson, 5215 Jackson Street, Omaha.
Mrs. J. C. Geiger, 50 Ventura Avenue, San Francisco.
Mrs. R. E. Mosiman, 2706 Tenth Avenue, North Seattle, Wash.
Mrs. E. W. Veal, 1936 San Marco Boulevard, Jacksonville, Fla.
Directors, two years—Mrs. Frank N. Haggard, 615 East Olmos Drive, San Antonio, Texas.
Mrs. James D. Lester, Granny White Pike, Nashville, Tenn.
Mrs. Claude L. Shields, 1234 East Seventh South Street, Salt Lake City.

CHAIRMAN OF STANDING COMMITTEES

Archives—Mrs. Herbert B. Henkel, 2135 Wiggins Avenue, Springfield, Ill.
Exhibits—Mrs. Ily R. Beir, 114 South Virginia Avenue, Atlantic City, N. J.
Finance—Mrs. James Blake, Hopkins, Minn.
Historian—Mrs. John J. Ryan, 2153 Iglehart Avenue, St. Paul.
Hygeia—Mrs. Eben J. Carey, 6119 West Wisconsin Avenue, Wauwatosa, Wis.
Legislation—Mrs. Arthur A. Herold, 1166 Louisiana Avenue, Shreveport, La.
Organization—Mrs. David W. Thomas, 112 West Main Street, Lock Haven, Pa.
Parliamentarian—Mrs. James F. Percy, 1030 South Alvarado Avenue, Los Angeles.
Press and Publicity—Mrs. James P. Simonds, 25 East Walton Place, Chicago.
Printing and Supplies—Mrs. Frank E. Coffey, 1910 Fort Street, Hays, Kan.
Program—Mrs. Walter F. Donaldson, 4724 Bayard Street, Pittsburgh.
Public Relations—Mrs. R. E. Mosiman, 2706 Tenth Avenue, North Seattle, Wash.
Revisions—Mrs. Arthur B. McGlothlan, 821 North Twenty-Fourth Street, St. Joseph, Mo.

Delaware

At an open meeting of the auxiliary to the Medical Society of Delaware in Wilmington February 27 the speakers were Dr. Warren S. Reese of the Hospital of the University of Pennsylvania and Mrs. Augustus S. Kech of Altoona, Pa.,

former president of the auxiliary to the American Medical Association. The meeting, which was largely attended by representatives of various organizations of the city and vicinity, was followed by a tea and reception.

Illinois

The auxiliary to the Chicago Medical Society held a meeting at the Medical and Dental Arts Building recently. Dr. Eben J. Carey, professor of anatomy and dean of the School of Medicine of Marquette University, Milwaukee, addressed the auxiliary on "Scientific Medicine and the Public." Honorary membership was conferred on Mrs. Rollo K. Packard, president-elect of the auxiliary to the American Medical Association, by Mrs. Frank G. Murphy, president of the auxiliary to the Chicago Medical Society.

Other meetings have been held by groups in various sections of the city. At the Irving Park Branch Mr. A. M. Simons of the American Medical Association was speaker; at the Jackson Park Branch Mrs. F. P. Hammond conducted a round table on "Socialized Medicine," and a paper was read on "Legislation in Relation to Medicine and Socialized Medicine"; at the North Shore Branch meeting Mr. J. E. Clegg, assistant special agent in charge of the Bureau of Investigation, U. S. Department of Justice, was speaker, and a paper on "State Medicine" was read by Mrs. H. P. Saunders.

Kansas

Dr. Martin Palmer addressed the auxiliary to the Sedgwick County Medical Society in February on "Child Speech Defects." The auxiliary to the Cloud County Medical Society recently assisted in the program of the Women's Field Army for the Control of Cancer in Concordia.

Through the efforts of the auxiliary to the Labette County Medical Society, announcement of the American Medical Association radio program has been regularly published in the *Parsons Sun*. The auxiliary to the Ford County Medical Society has placed *Hygeia* in fifteen grade schools in the district this year and will place it in the rural schools for a six months' period beginning September 1939.

Missouri

The auxiliary to the Cass County Medical Society recently gave a special program in honor of pioneer physicians of the state.

The auxiliary to the Jackson County Medical Society held an Endowment Tea recently for the benefit of the Jackson County Medical Society Library. At a luncheon meeting of the auxiliary at St. Joseph Hospital recently, Rabbi Samuel S. Mayerberg was the speaker.

Dr. James S. Chapman, director of the Bureau of Child Hygiene of the State Board of Health, addressed the auxiliary to the Cole County Medical Society on "Problems of Maternal and Infant Welfare as Handled by the State Board of Health."

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ARKANSAS

Dr. Cromer Appointed Dean at Arkansas.—Dr. Stuart P. Cromer of the staff of the Council on Medical Education and Hospitals, American Medical Association, Chicago, has been appointed dean of the University of Arkansas School of Medicine, Little Rock, succeeding Dr. Frank Vinsonhaler. Dr. Cromer graduated at Northwestern University Medical School, Chicago, in 1935. From 1935 to 1937 he was assistant superintendent of the Illinois Research and Educational Hospital, Chicago. He was medical director of Baylor University Hospital, Dallas, Texas, from 1937 until April 1938, when he joined the staff of the American Medical Association.

CALIFORNIA

Mussels Placed Under Quarantine.—A quarantine order has again been issued by the state department of health prohibiting the taking, sale or offering for sale of mussels gathered along the ocean shore from the southern boundary of Los Angeles County to the California-Oregon boundary line, excepting the bay of San Francisco. The ban is effective from June 1 to September 30.

Dr. Stampar to Have New Post at California.—Dr. Andrija Stampar, professor of social medicine, State University, Zagreb, Yugoslavia, has been named to the newly created post of Rosenberg professor in the public social sciences at the University of California, Berkeley. Dr. Stampar will be the first to hold the position, which was created by a gift from the Rosenberg Foundation of San Francisco. A graduate of the University of Vienna, Dr. Stampar formerly served as director of health of Yugoslavia. He was adviser on health matters to the National Government of the Chinese Republic from 1933 to 1936, when he became expert on health matters to the health section of the League of Nations. In 1938 he was a visiting lecturer under the Rockefeller Foundation in the United States. While on the Berkeley campus he will give two courses, one for graduate students and one for upper division students. He will also deliver a series of public lectures on the campus and, by special conditions of the foundation grant, will be enabled to visit other parts of the state for lectures and consultations, according to the university *Clip Sheet*.

COLORADO

Mid-Summer Radiological Conference.—The Mid-Summer Radiological Conference will be held in Denver July 24-29 under the auspices of the Denver Radiological Club. According to the preliminary program, the guest speakers will be: Drs. Hans A. Jarre, Detroit; James F. Kelly, Omaha; Sherwood Moore, St. Louis; Bernard H. Nichols, Cleveland; Wendell G. Scott, St. Louis; Paul F. Titterington, St. Louis, and Mrs. Edith H. Quimby and Helen Quincy Woodard, Ph.D., both of New York. There will be round table discussions on miscellaneous subjects and symposiums on the radiation therapy of inflammations; radiation therapy of the diseases of the blood and the blood forming organs, and urology.

CONNECTICUT

Society News.—The Yale Medical Society was addressed May 10 by Dr. Thomas Francis Jr., New York, on "Studies of Immunity to the Virus of Epidemic Influenza." The society was addressed April 17 by F. G. Young, Ph.D., London, on "The Influence of Diabetogenic Pituitary Extract on Normal Animals."—The New Haven Ophthalmological Society was organized April 17; officers include Drs. Eugene M. Blake, New Haven, president, and Frederick A. Wies, New Haven, secretary.

State Medical Election.—Dr. Arthur B. Landry, Hartford, was chosen president-elect of the Connecticut State Medical Society at the recent annual session and Dr. Joseph I. Linde, health officer of New Haven, was installed as president. Other officers include Drs. Charles E. Sanford, New Haven; Wilmarth Bradford Walker, Cornwall, vice presidents; Creighton

Barker, New Haven, executive secretary. The 1940 convention will be held in Hartford. The society voted at this meeting to employ a full time executive secretary commencing Jan. 1, 1941, as recommended by the council; for this purpose the dues for 1940 were set at \$15. Endorsement was also given to house bill 106 creating a commission to study the problem of physical and mental disabilities among the people of the state and methods for prevention and care.

ILLINOIS

Society News.—At a meeting of the Madison County Medical Society in Madison June 2 the speakers were Drs. James E. Graham, Springfield, "Backache"; Walter R. Fischer, Chicago, "Common Disorders of the Foot," and Emil D. W. Hauser, Chicago, "Derangements of the Knee Joints."

Postgraduate Courses in Obstetrics and Pediatrics.—The departments of obstetrics and pediatrics of the University of Illinois cooperating with the staffs of the medical schools of Chicago and the state department of public health will again offer a series of one week courses at the Research and Educational Hospital, Chicago. Each course begins Monday morning at 9 o'clock and ends at noon on Saturday. The courses will open July 10 and end with the week of August 28. The registration is limited to twenty; physicians outside Chicago will be given the preference. The registration fee of \$10 should be sent with the application to Mr. G. R. Moon, 1853 West Polk Street, Chicago.

Chicago

Course in Electrocardiography.—The cardiovascular department of Michael Reese Hospital will conduct a full time course in electrocardiography, August 21-September 2, under the direction of Dr. Louis N. Katz, director of cardiovascular research. Reservations may be made on receipt of \$10, which will be applied on the tuition. Additional information may be obtained from the hospital, Twenty-Ninth Street and Ellis Avenue.

Course in Syphilis.—A postgraduate course in syphilis is being offered by the department of dermatology of the University of Illinois College of Medicine in cooperation with various departments of the university. A grant from the federal government with the approval of the state department of public health is financing the course. With lectures, laboratory demonstrations and the presentation of hospital and dispensary clinical material, the course is designed to offer to the practitioner a review of the subject and a discussion of recent developments. The first period of the course, which will continue for one week, opened June 19. It will be repeated once each month during the summer. Only licensed physicians will be accepted. The number of registrants for any one period will be limited to twenty and the course will not be offered to less than six. Those registering will be accepted in the order of application. Applications together with a check covering the registration fee of \$10, made payable to the University of Illinois, should be sent to the Examiner and Recorder, 1853 West Polk Street.

Dr. Sappington Wins First Knudsen Award.—Dr. Clarence O. Sappington, Chicago, received the first W. S. Knudsen Award for the most outstanding contribution to industrial medicine during 1938-1939. The award was made on the basis of his book "Medicolegal Phases of Occupational Diseases." Mr. W. S. Knudsen, president of the General Motors Corporation, made the presentation at the annual meeting of the American Association of Industrial Physicians and Surgeons in Cleveland June 7. Dr. Sappington graduated at Stanford University School of Medicine, San Francisco, in 1918. He has had extensive industrial affiliations, serving, among other things, as assistant surgeon, U. S. Public Health Service; medical director, western division, Montgomery Ward & Company, and director of the division of industrial health, National Safety Council, Chicago. Since 1932 he has been a consultant in industrial hygiene, industrial medicine and occupational diseases. He is said to be the first American to receive the degree of doctor of public health in the field of industrial hygiene, conferred by Harvard University in 1924.

IOWA

Clinical Meeting in Iowa City.—Dr. Raymond S. Grossman, Marshalltown, was elected president of the Iowa Clinical Medical Society at its meeting in Iowa City April 14; Dr. Ernest E. Shaw, Indianola, vice president, and Dr. James Stuart McQuiston, Cedar Rapids, secretary-treasurer. Members of the staff of the State University of Iowa College of Medicine

were among the speakers: Drs. Horace M. Korn, "Influence of Pulmonary Emphysema on the Heart"; Harry P. Smith, "Possible Uses of Purified Thrombin"; Ruben Flocks, "Treatment of Renal Calculi"; James A. Greene, "Treatment of Hypoparathyroidism with A T-10," and Alto E. Feller, "Treatment of Hay Fever."

KENTUCKY

Dr. Abell Honored.—Dr. Irvin Abell, Louisville, immediate past president of the American Medical Association, received the honorary degree of doctor of laws, honoris causa, at the annual commencement of Marquette University, Milwaukee, June 9. Dr. Abell was similarly honored by Georgetown University, Washington, D. C., with the degree of doctor of science, conferred June 3.

Society News.—Dr. Harry Beckman, Milwaukee, addressed the Jefferson County Medical Society, Louisville, June 5, on chemotherapy. Drs. Argus D. Willmoth and Winston U. Rutledge, Louisville, addressed the society June 19 on "Treatment of Carbuncles" and "Annular Skin Lesion of the Body Mistaken for Ringworm Infection" respectively.—Dr. Moses W. Howard, Harlan, addressed the Letcher County Medical Society, Whitesburg, recently on "Gonorrhea and Its Complications."—Dr. Wiley E. McWilliams, Brodhead, recently addressed the Rockcastle County Medical Society, Mount Vernon, on dementia praecox.—Dr. Charles B. Johnson, Russell, addressed the Greenup County Medical Society, Greenup, May 12 on treatment of pneumonia with sulfapyridine.

MAINE

Society News.—The Portland Medical Club devoted its meeting April 4 to a symposium on the liver with the following speakers: Drs. Donald H. Daniels, Langdon T. Thaxter, Mortimer Warren, William D. Anderson and George A. Tibbetts.—At a meeting of the Kennebec County Medical Association in Togus May 18, the speakers were Drs. Charles P. Shelton, Boston, on "Bleeding During Pregnancy" and Joseph H. Shortell, Boston, "Treatment of Fractures of the Neck of the Femur." The society held a clinical session.—Dr. Siegfried J. Thannhauser, Boston, addressed the Knox County Medical Association in Rockland April 11 on "Vitamin Deficiencies."—Dr. Richard H. Overholt, Brookline, Mass., among others, discussed "Some New Developments in the Management of Chest Lesions" before the Cumberland County Medical Society April 21.

MASSACHUSETTS

Symposium on Carcinoma of the Tongue.—The staffs of the Massachusetts General, Collis P. Huntington Memorial, Pondville and Palmer Memorial hospitals arranged a symposium on carcinoma of the tongue June 13 at the Palmer Memorial Hospital, Boston. A review of cases seen at each of the hospitals was presented by Drs. Roy E. Mabrey, Ira T. Nathanson, Thomas J. Anglem and Clifford C. Franseen.

MINNESOTA

Personal.—Dr. Paul A. O'Leary, Rochester, has been appointed a member of the National Advisory Health Council.—Dr. Ruth E. Boynton, associate professor of preventive medicine and public health, University of Minnesota Medical School, Minneapolis, has been appointed to the state board of health.—Dr. William Randolph Lovelace II, Rochester, gave a lecture at Guy's Hospital, London, recently on the use of high concentrations of oxygen and of helium and oxygen mixtures.—Dr. James T. Christison, St. Paul, has resigned as a member of the editing and publishing committee of the state medical society, ending twenty years' service. He has been succeeded by Dr. Gage Clement, Duluth. Dr. Christison served as president of the Ramsey County Medical Society in 1917 and of the Minnesota State Medical Association in 1929. Recently he has been a member of the House of Delegates of the American Medical Association.

MISSOURI

State Medical Election.—Dr. Cyrus E. Burford, St. Louis, was chosen president-elect of the Missouri State Medical Association at its recent annual session and Dr. James R. McVay, Kansas City, was installed as president. Mr. Elmer H. Bartelsmeyer, St. Louis, who has been assistant secretary for a number of years, was appointed executive secretary of the association at this meeting. The next annual session will be held in Joplin, the date to be determined later.

MONTANA

Annual Clinic.—The Yellowstone Valley Medical Society held its annual spring clinic in Billings May 1. Among the speakers were Drs. Robert F. E. Stier, Spokane, Wash., on allergy; Richard R. Chapple, some common rectal conditions; Harry O. Drew, goiter; Wayne Gordon, collapse therapy in tuberculosis outside the sanatorium, and Dolon Ernest Hodges, obstructions of the lower genito-urinary tract.

NEBRASKA

State Medical Meeting and Election.—The seventy-first annual meeting of the Nebraska State Medical Association was held in Grand Island May 1-4. The following guests appeared on the scientific program:

Dr. Archibald F. O'Donoghue, Sioux City, Iowa, Fractures of the Hip—A Plea for Internal Fixation.

Dr. J. Albert Key, St. Louis, Treatment of Compound Fractures.

Dr. Oscar L. Miller, Charlotte, N. C., Miscellaneous Use of Metal Fixation in Bone Surgery.

Dr. Edward H. Ryncarson, Rochester, Minn., Practical Suggestions in the Treatment of Diabetes Mellitus.

Dr. Franklin G. Ebaugh, Denver, The Psychoneuroses in the General Practice of Medicine.

Dr. James Kerr Anderson, Minneapolis, The Itching Anus; Office Treatment of Rectal and Anal Diseases.

Dr. Grayson L. Carroll, St. Louis, Early Prostatism; The Urologist Turns to Medicine.

Dr. French K. Hansel, St. Louis, Nasal Allergy; Recent Advances in the Diagnosis and Treatment of Nasal and Sinus Disease.

Dr. Robert L. Schaefer, Detroit, Glandular Preparations—Uses and Abuses; Diagnosis and Treatment of Sexual Immaturity.

At the annual dinner Dr. Rock Sleyster, Wauwatosa, Wis., then President-Elect of the American Medical Association, spoke on "Medical Problems of the Day" and Dr. Ebaugh on "A State Program for Mental Health." Dr. Clayton F. Andrews, Lincoln, was named president-elect; Drs. Glen E. Peters, Randolph, and Henry R. Miner, Falls City, were elected vice presidents and Dr. Roy B. Adams, Lincoln, reelected secretary. Dr. Arthur L. Miller, Kimball, is the president for 1939.

NEW JERSEY

State Medical Election.—Dr. Watson B. Morris, Springfield, was chosen president-elect of the Medical Society of New Jersey at the annual meeting in Atlantic City June 6-8 and Dr. Edward Mathias Zeh Hawkes, Newark, was installed as president. Dr. Thomas K. Lewis, Camden, was named first vice president and Dr. Elias J. Marsh, Paterson, second vice president. Honorary awards were presented to Drs. Andrew F. McBride for outstanding service as mayor of Paterson and in other civic and medical activities; Stanley H. Nichols, Long Branch, for his work on the state board of health; Berthold S. Pollak, Jersey City, for work among the tuberculous, and Edward J. Ill, Newark, as a pioneer surgeon.

NEW MEXICO

State Medical Election.—Dr. William B. Cantrell, Gallup, was chosen president-elect of the New Mexico Medical Society at the annual meeting in Gallup May 12, and Dr. George T. Colvard, Deming, was installed as president. Dr. Leo B. Cohenour, Albuquerque, is secretary. The 1940 session will be held in Albuquerque.

NEW YORK

Society News.—Dr. Hugh H. Young, Baltimore, addressed the Medical Society of the County of Albany May 24 on "Genital Abnormalities, Hermaphroditism and Related Adrenal Diseases."—At a meeting of the Dutchess County Medical Society at Castle Point May 11 the speakers were Drs. Samuel A. Beddall on "Pathologic Indications for Collapse Therapy in Pulmonary Tuberculosis"; Clarence J. Goebel, "Surgical Treatment of Pulmonary Tuberculosis," and Reuben I. Shapiro, "Thoracoplasty in the Fifth and Sixth Decades."—Dr. Winfield W. Scott, Rochester, addressed the Oswego County Medical Society, Oswego, May 24 on diseases of the prostate.—Dr. Maurice J. Whitelaw, Binghamton, addressed the Broome County Medical Society, Binghamton, May 9 on "A Theoretical and Clinical Consideration of Ovarian Hormones."

New York City

Fund for Research in Bacteriology and Sanitary Science.—The New York Academy of Medicine announces the establishment of the Robert Livingston Seaman Fund by the terms of the will of the late Dr. Seaman. The academy has \$600 for assignment in 1939 for research in bacteriology or

sanitary science, either as grants for investigation or scholarships for research. Expenditures may be made for technical help, aid in publishing original work and purchase of necessary books or apparatus. Applications will be received from institutions or individuals up to September 15 by a committee of which Dr. Wilson G. Smillie is chairman. Communications should be addressed to Dr. Smillie at 2 East One Hundred and Third Street.

NORTH CAROLINA

State Medical Meeting and Cruise.—The Medical Society of the State of North Carolina held its annual session during a cruise to Bermuda, May 9-14. Sessions were held on board the *Queen of Bermuda* and the party spent two days in Hamilton in sightseeing and entertainment. Dr. Hubert B. Haywood, Raleigh, was named president-elect and Dr. William Allan, Charlotte, was installed as president. Drs. Franklin Webb Griffith, Asheville, and Franklin C. Smith, Charlotte, were elected vice presidents. Among the speakers were Drs. Alexis F. Hartmann, St. Louis, and Benjamin P. Watson, New York.

Tuberculosis Seminar.—The Buncombe County Medical Society will present its third annual seminar on tuberculosis at the Medical Library in Asheville July 10-16. In addition to addresses on various phases of tuberculosis, there will be clinical conferences, demonstrations of artificial pneumothorax and of laboratory procedures and visits to the U. S. Veterans' Administration Facility at Oteen and to the State Sanatorium at Black Mountain. There will be one evening meeting when Dr. David T. Smith, Durham, will speak on "The Harmful Effect of Routine Therapy for Tuberculosis When Applied to Nontuberculous Conditions Simulating Tuberculosis." Dr. Karl Schaffle, Asheville, is chairman of the seminar.

OHIO

Society News.—Dr. Paul I. Hoxworth, Cincinnati, addressed the Montgomery County Medical Society, Dayton, May 19 on blood transfusion.—Dr. August A. Werner, St. Louis, addressed the Mahoning County Medical Society, Youngstown, June 20 on "The Influence of the Ductless Glands on Growth and Development."

Student Prizes at Western Reserve.—Jacob B. Tuckerman, a member of the 1939 graduating class at Western Reserve University School of Medicine, Cleveland, received the senior prize in surgery, the gift of Dr. Elliott C. Cutler, Boston, formerly of the medical school faculty. Mr. Tuckerman also received the senior prize in obstetrics, the gift of the late Dr. Edwin C. Garvin. R. Wenner Machamer, member of the freshman class, received the Dr. Herbert S. Steuer prize for special work in anatomy.

PENNSYLVANIA

Personal.—Dr. Frederick W. Heyer, surgeon in chief of the Nanticoke State Hospital, was honored with a testimonial dinner April 30 by thirty-nine physicians of the staff and vicinity, marking twenty-five years of service.—Drs. Seymour T. Schmehl, Reading, and James G. Matternes, Sinking Spring, were approved for affiliate membership by the Berks County Medical Society at a recent meeting. Dr. Schmehl has been a member since 1892 and Dr. Matternes since 1903.—Dr. Samuel O. Pruitt, Philadelphia, has resigned as medical secretary of the Pennsylvania Tuberculosis Society and Dr. Clarence R. Phillips, Harrisburg, has taken over his duties for a year with the title of medical supervisor.

Philadelphia

Personal.—Mr. Steven M. Spencer, science reporter of the Philadelphia *Evening Bulletin*, has received a Nicman Fellowship for a year of study at Harvard University, Cambridge, Mass. These fellowships were established in 1937 through a gift to Harvard from Mrs. Agnes W. Nicman, widow of the founder of the Milwaukee *Journal*, to give newspapermen an opportunity for an academic year of unrestricted study in special fields. Mr. Spencer, a native of Omaha, graduated from the University of Pennsylvania in 1928 and joined the *Bulletin* the same year. He has specialized in science since 1933. At Harvard he will study physiology, chemistry, anthropology, physics, sociology and the history of science.

Three Deaths from Spotted Fever.—Nine cases of Rocky Mountain spotted fever with three deaths have been reported from Philadelphia and the adjoining area in Delaware, according to newspaper reports. The state department of health has arranged for immediate blood tests in state laboratories, and physicians are urged to send specimens from suspected cases.

The Philadelphia County Medical Society and the College of Physicians of Philadelphia, through their committees on preventive medicine, have asked all persons who have tick-infested dogs to remove the ticks alive and send them to Jefferson Medical College, where a research group has arranged a study to determine what proportion of ticks are carriers of the spotted fever organism. Last year there were seven deaths from the disease in the Philadelphia area, it was reported. Arrangements have been made with the U. S. Public Health Service for distribution of vaccine through the state department of health.

RHODE ISLAND

New State Medical Board.—A new board of medical examiners was recently appointed for Rhode Island. Following are the members: Drs. Wilfred Pickles and Robert M. Lord; Providence, and James H. Prior, Cranston.

Society News.—Dr. Paul W. Preu, New Haven, Conn., addressed the Rhode Island Society for Neurology and Psychiatry recently on "Symptomatic Psychoses with Special Reference to Bromide Intoxications" and Dr. Edwin F. Gildea, New Haven, on "Relationship of Vitamin Deficiencies to Neurological and Psychiatric Problems."

WASHINGTON

Hospital News.—Dr. Thomas J. Fatherree Jr., Birmingham, Ala., has been appointed head of the new McKay Memorial Research Hospital at Soap Lake for the treatment of Buerger's disease.

Plague Infection.—According to *Public Health Reports*, plague infection was proved in a pool of forty-four fleas collected from four ground squirrels, *Citellus townsendi*, shot April 25 at a location 4 miles west of Rocky Ford and 17 miles northwest of Ritzville, Lincoln County.

WEST VIRGINIA

Society News.—Drs. Robert King Buford and Pat A. Tuckwiller, Charleston, addressed the Logan County Medical Society, Logan, May 10 on "Surgical Aspects of Duodenal Ulcer" and "Diagnosis and Medical Management of Duodenal Ulcer" respectively.—Dr. William M. Sheppe, Wheeling, addressed the Monongalia County Medical Society, Morgantown, May 2 on "Classifications and Methods of Treatment of Syphilis of the Central Nervous System."—Dr. Philip W. Brown, Rochester, Minn., addressed the Kanawha Medical Society, Charleston, May 9 on "Diagnosis and Management of the Irritable Colon Syndrome."—Dr. Eldridge L. Eliason, Philadelphia, addressed the Ohio County Medical Society, Wheeling, May 5 on "Surgical Jaundice."

WISCONSIN

Institute on Blood and Blood-Forming Organs.—The University of Wisconsin Medical School, Madison, announces an Institute for the Consideration of the Blood and Blood-Forming Organs September 4-6. The program will include papers and round table discussions by European and American workers in the field of hematology. The following papers will be presented:

- Dr. L. J. Witts, Oxford, England, Anemias Due to Iron Deficiency.
- Dr. E. Meulengracht, Copenhagen, Denmark, Some Etiologic Factors in Pernicious Anemia and Related Macrocytic Anemias.
- Dr. Cecil J. Watson, Minneapolis, The Porphyrins and the Diseases of the Blood.
- Dr. Cornelius P. Rhoads, New York, Aplastic Anemia.
- Dr. Harry Eagle, Baltimore, The Coagulation of Blood.
- Dr. George R. Minot, Boston, Anemias of Nutritional Deficiency.
- Dr. Russell L. Haden, Cleveland, The Nature of the Hemolytic Anemias.
- Dr. Jacob Furth, New York, Experimental Leukemia.
- Dr. Claude E. Forkner, New York, Monocytic Leukemia and Aleukocytic Hematemia.
- Dr. Edward B. Krumbhaar, Philadelphia, Hodgkin's Disease.
- Dr. Louis K. Diamond, Boston, The Erythroblastic Anemias.
- Dr. Edwin E. Osgood, Portland, Ore., Marrow Cultures.
- Dr. Charles A. Doan, Columbus, Ohio, The Reticulo-Endothelial System.
- Hal Downey, Ph.D., Minneapolis, Infectious Mononucleosis.
- Dr. Paul Reznikoff, New York, Polycythemia.

Physicians and others interested are invited to attend the institute. Information may be obtained from Dr. Ovid O. Meyer, chairman of the program committee, University of Wisconsin Medical School, Madison, or from the University News Bureau, 711 Langdon Street, Madison.

GENERAL

New Fellows of American Academy of Arts and Sciences.—At the annual meeting of the American Academy of Arts and Sciences in Boston May 10 the following were elected new fellows: Gregory Pincus, Sc.D., Harvard University,

Cambridge, Mass.; Drs. Arturo Rosenbluth and William Thomas Salter, Harvard Medical School, Boston, and Dr. Frederick F. Russell, Boston. Dr. Walter B. Cannon, Boston, was elected vice president for class II of the academy.

Students in Extramural Schools Barred by National Board.—The National Board of Medical Examiners at its annual meeting April 23 made a ruling that students matriculating after July 1 in the extramural schools of Scotland and Ireland would not be admitted to the board's examination. The schools affected are: St. Mungo's College and Anderson College, Glasgow; School of Medicine of the Royal Colleges, Edinburgh, and the Royal College of Surgeons, Dublin. Dr. Norris W. Vaux, Philadelphia, was elected a member of the board for the division in obstetrics. The licensing boards of New York and New Jersey have recently taken similar action on the extramural schools.

Science Congress to Have Health Section.—The Sixth Pacific Science Congress will be held at the University of California, Berkeley, July 24 to August 12. The main divisions of the program of the public health and nutrition section will deal with epidemiology of diseases of the Pacific Basin; nutritional problems, industrial hygiene and health education. Dr. Karl F. Meyer of the Hooper Foundation for Medical Research, University of California, San Francisco, is general chairman for this program and Leland S. McClung, Ph.D., also of the Hooper Foundation, is secretary. Dr. Royd R. Sayers, U. S. Public Health Service, will be chairman of the sessions on industrial hygiene; Agnes Fay Morgan, Ph.D., University of California, Berkeley, nutrition, and Dr. William P. Shepard, Stanford University School of Medicine, San Francisco, public health education.

Regional Meeting on Physical Therapy.—The South-eastern section of the American Congress of Physical Therapy is holding its first scientific session July 10 in Jacksonville, Fla. Among the papers to be presented are:

- Dr. Edward F. Carter, Tampa, Fla., Ultraviolet Radiation.
- Dr. Charles E. Irwin, Warm Springs, Ga., Obscure Deformities in Poliomyelitis.
- Dr. Hal M. Davison, Atlanta, Evaluation of Hyperpyrexia in General Medicine.
- Dr. Abraham R. Hollender, Miami Beach, Fla., Short Wave Diathermy in Nasal Sinusitis.
- Drs. Lawson Thornton and James Calvin Sandison, Atlanta, Relation of Physical Therapy to Orthopedics.

At an evening session there will be addresses by the following:

- Howard A. Carter, B.S. in M.E., secretary, Council on Physical Therapy, American Medical Association, Chicago, The Work and Function of the Council on Physical Therapy.
- Dr. Frank H. Krusen, Rochester, Minn., Physical Treatment of Arthritis.
- Dr. Nathan H. Palmer, New Orleans, The Value of Physical Therapy in Industrial Medicine.

Symposium on Visual Fatigue.—Representatives of several research interests and institutions attended a symposium on visual fatigue in Washington, D. C., May 20-21. The gathering was held at the suggestion of the committee on scientific aids to learning of the National Research Council, which will probably undertake research in the general field of visual fatigue. Among the speakers were:

- Walter R. Miles, Ph.D., New Haven, Conn., The Visual Fatigue Problem.
- George Wald, Ph.D., Biological Laboratories, Harvard University, Cambridge, Mass., The Chemical Basis of Visual Adaptation.
- Clarence H. Graham, Ph.D., Psychology Laboratory, Brown University, Providence, R. I., Frequency of Nerve Impulse Discharge as a Function of Time After Onset of Illumination.
- Selig Hecht, Ph.D., New York, Relation Between Visual Acuity and Illumination.
- Brian O'Brien, Ph.D., Institute of Optics, University of Rochester, Rochester, N. Y., Iris Measurements.
- Perley G. Nutting Jr., Research Laboratories, Eastman Kodak Company, Rochester, N. Y., The Influence of Flicker Fatigue on Flicker Frequency.
- Dr. Alfred Bielschowsky, Dartmouth Medical School, Hanover, N. H., Influence of Fatigue on the Mechanism Involved in Binocular Cooperation.
- Frank K. Moss, Lighting Research Laboratory, General Electric Company, Nela Park, Cleveland, Visibility and Ease of Seeing.
- Ross A. McFarland, Ph.D., Fatigue Laboratory, Harvard Medical School, Boston, The Effects of Anoxia on Certain Visual Functions.
- Miles A. Tinker, Ph.D., Psychology Laboratory, University of Minnesota, Minneapolis, Visual Fatigue in the Reading of Print.
- Dr. Walter F. Dearborn, Psycho-Educational Clinic, Harvard University, Cambridge, On the Relations of Visual Fatigue to Reading Disability.
- Dr. Robert K. Lambert, Institute of Ophthalmology, Columbia University, New York, The Spasmogenic Tendency and Its Effect on the Eyes.
- Harry M. Johnson, Ph.D., Department of Psychology, Tulane University, New Orleans, Rival Motions of the Nature of Physiological Impairment.

Special Society Elections.—Dr. Albert C. Snell, Rochester, N. Y., has resigned as president-elect of the American Academy of Ophthalmology and Otolaryngology because of ill health and Dr. Frank E. Brawley, Chicago, has been elected by the council of the academy to succeed him. Dr. Brawley will take office Jan. 1, 1940.—Dr. Robert L. Benson, Portland, Ore., was named president-elect of the American Society for the Study of Allergy at the annual meeting in St. Louis May 14-15. Dr. Warren T. Vaughan, Richmond, Va., became president; Dr. Milton B. Cohen, Cleveland, was elected vice president and Dr. James Harvey Black, Dallas, Texas, secretary.—Dr. Richard B. Dillehunt, Portland, Ore., was elected president of the Pacific Coast Surgical Association at its annual meeting in San Francisco and Del Monte, Calif., in March and Dr. William A. Taylor, Ellensburg, Wash., vice president. The 1940 meeting will be held in Portland.—Dr. Gustav L. Kaufmann, Chicago, was elected president of the American Association of Medical Milk Commissions at its annual meeting in St. Louis May 15-16. Dr. Paul B. Cassidy, Philadelphia, was reelected secretary.—Dr. Austin A. Hayden, Chicago, was elected president of the American Society for the Hard of Hearing at the annual meeting in New York in June.—Dr. Benjamin P. Potter, Jersey City, N. J., was elected president of the American Academy of Tuberculosis Physicians at the annual meeting in St. Louis in May. Vice presidents elected were: Drs. John B. Crouch, Colorado Springs, Colo., and James H. Stygall, Indianapolis; Dr. Arnold Minnig, Denver, was reelected secretary.—Dr. Henry H. Turner, Oklahoma City, was elected president of the American Therapeutic Society at the annual meeting in St. Louis May 13. Vice presidents elected were Drs. Garold V. Stryker, St. Louis; Chevalier L. Jackson, Philadelphia, and Edwin C. Hamblen, Durham, N. C. Dr. Oscar B. Hunter, Washington, D. C., was elected secretary.—Dr. James A. Babbitt, Philadelphia, was elected president of the American Laryngological Association at the annual meeting in Rye, N. Y., May 24-26, and Dr. Charles J. Imperatori, New York, secretary.

FOREIGN

British Medical Association.—The one hundred and seventh annual meeting of the British Medical Association will be held in Aberdeen, Scotland, July 21-28. The scientific meetings will be in sixteen sections meeting July 26-28, the preceding days being occupied with the "annual representative meeting" and other preliminary conferences. Among the speakers at the section meetings will be Drs. Philip D. Wilson, New York, who will open a discussion of "The Painful Shoulder"; Winchell McK. Craig, Rochester, Minn., "The Surgical Treatment of Hypertension" and Chevalier Jackson, Philadelphia, "The Role of the Bronchoscopist in the Diagnosis and Treatment of Bronchopulmonary Disease." Dr. Colin D. Lindsay, Plymouth, is president and Dr. Thomas Fraser, Aberdeen, president-elect of the association.

Medical Center in Jerusalem Dedicated.—The Rothschild-Hadassah-University Hospital and Medical School on Mount Scopus overlooking Jerusalem was dedicated May 9 with a meeting of the committees that have worked toward its establishment, members of the medical center staff and of the Associated Hadassah Medical Organization of Palestine. Miss Henrietta Szold, Jerusalem, honorary president of Hadassah, the women's Zionist organization of America; Dr. Judah L. Magnes, president of Hebrew University, and Mr. Salman Schocken, president of the university's executive committee, were the principal speakers. Units of the center are: the Rothschild-Hadassah-Hebrew University Hospital, the Henrietta Szold School of Nursing and the Nathan Ratnoff Medical School for Postgraduate Teaching and Research. Funds for its construction, which cost \$1,250,000, were raised by Hadassah and the American Jewish Physicians' Committee, the latter headed by Dr. Nathan O. Ratnoff, New York. Dr. Julius Jarcho, New York, collected a medical library for the new center and Dr. Jacob J. Golub, New York, was honorary consultant on the architecture. The hospital will have facilities for 300 beds and may later be expanded. The school of nursing will accommodate eighty pupils and ten graduate nurses for a three year course. The medical school has 100 rooms, a large animal house and facilities for research in cancer, experimental pathology, parasitology, bacteriology, chemistry and endocrinology.

Injuries to Both Semilunar Cartilages

Injury to one semilunar cartilage of the knee joint, usually the internal, is well known, but injuries to both cartilages do not seem to have been described. Yet at the Section of Orthopaedics of the Royal Society of Medicine Mr. Constantine Lambrinudi reported eight cases which he had seen in the last two years. In six of the cases there was pain on the inner side. In four the disability was attributed to quadriceps insufficiency and treated as such for a long time. The pain on the inner side is interesting because the statement is made that pain due to a lesion of the external cartilage is often referred to the inner side. Mr. Lambrinudi suggested that in these cases it was not a true referred pain but that there was a lesion of the internal cartilage as well. The practical importance of this suggestion is that on account of pain on the inner side the surgeon may be tempted to explore the inner cartilage first and, finding something definitely abnormal, may be lulled into the belief that this is the cause of the trouble and think it not necessary to explore the outer side of the joint. This happened in four of the cases. The following is an example:

About three years ago a girl twisted her knee playing tennis. She had immediately a large effusion and great pain, most marked on the inner side. There was some lateral wobble and an orthopedic surgeon diagnosed strain of the internal lateral ligament and put the leg in plaster. After this the knee never felt strong and she had attacks of "the whole knee going out" with pain on the inner side. About a year later another orthopedic surgeon operated and appeared to have removed the anterior half of the internal cartilage. But her symptoms persisted and when she was examined by Mr. Lambrinudi there was marked ligamentous laxity and muscular atony, and when she was anesthetized he felt a definite click in the external cartilage. He explored the posterior half of the internal cartilage and found it intact except for a small tag. It came away as one piece and there was no doubt that the anterior half had previously been removed. He then explored the outer side and found that the external cartilage, though not displaced, was extremely movable. The posterior part came forward with the slightest pull and he was able to remove the cartilage complete. Since the operation the knee only twice has let her down and for this there was a definite cause, such as slipping over a rug. She could hike, dance and run comfortably but did not feel secure when side stepping. Before the operation attacks were much more frequent and occurred unaccountably. So in spite of some ligamentous laxity the removal of both cartilages improved her symptoms.

Mr. Lambrinudi drew the following conclusions from his cases: 1. Dual lesions of the semilunar cartilages occur more frequently than is realized and ought to be suspected in all cases where the pain, associated with an injury to the external cartilage, is alleged to be referred to the inner side. 2. Dislocation of the external cartilage is more likely to be associated with strain of the crucial ligaments than is the case with internal cartilages. 3. The diagnosis of quadriceps insufficiency should be abolished, as it gives rise to confusion of thought. 4. Alarming symptoms associated with a moderate degree of ligamentous laxity are really due more to slipping in and out of the external cartilage than to laxity itself, and in these circumstances excision of this cartilage is a sound procedure.

New Neurologic Research Institute

A new well equipped building for investigation into the causes of mental defects and abnormalities and borderline conditions has been opened at Bristol by the secretary of state for the dominions in the presence of a distinguished company of neurologists. It is called the Burden Neurological Research Institute because it has been made possible by the munificence of Mrs. R. G. Burden, warden of Stoke Park Colony for Mental Deficients, within the grounds of which the new building has been erected. Professor Golla is to be the director, and the staff will consist of Mr. Grey Walter (electrophysiology), Dr. Max Reiss (a Czech endocrinologist), Mr. N. S. L. MacLeod and Mr. A. Tingey (biochemist) and Mr. Wylie McKissock (visiting surgeon).

Among those present was Dr. P. O'Brien, representative in Paris of the Rockefeller Foundation, which has made a generous contribution to the neurosurgical department. The Medical Research Council has also made a grant in support of some of the research work. The director, Professor Golla, said that only those who had realized how the multiplicity of competing claims hampered the work of the large hospital clinics would fully appreciate the advantages of such a research institute, which was equipped in the very best way for the investigation not only of the functions of the nervous system but of the body as a whole. In the preoccupation with the brain there was some tendency to forget the bodily stratum of mental disease. It was intended to take a few carefully selected cases and investigate them by every means available to electrophysiology and endocrinologic research. An immediate occupation would be the study of the varied group of pathologic states of the brain which were responsible for epileptic seizures. What the neurologist called epilepsy was the least understood of the common nervous diseases. It was hardly an exaggeration to say that our knowledge had received little addition since the time of Galen until certain researches, carried out chiefly in America and this country, had given hints for further investigation. There were now good grounds for hoping that certain electrophysical methods would enable us to understand and combat this distressing disease.

The International Organization Against Trachoma

The International Organization Against Trachoma was created in 1929 by the thirteenth Ophthalmic Congress to study trachoma. The president is Dr. MacCallan of London. Annual meetings are to be held and will be open to all practitioners. The annual subscription will be \$6, which includes the quarterly journal *Revue internationale du trachome*. Without the journal the annual subscription is \$3. The journal has been published in Paris since 1924 by the *Ligue contre le trachome*. It contains articles in various languages and in 1936 was recognized as the mouthpiece of the organization. The annual subscriptions of members are not sufficient for the ordinary expenses of the organization, and donations are invited from ophthalmologic societies, governments and private persons.

Edward Wing Twining

The death at the early age of 52 of Edward Wing Twining is a great loss to British radiology. He qualified in 1913 and after some experience in general practice and holding various hospital appointments was given charge of the electrotherapeutic department at a military hospital during the war. In collaboration with a surgeon, H. S. Souttar, he published his investigations on the treatment of injuries of the peripheral nerves. He then took up radiology and on obtaining his diploma in that subject was offered by the examiner, A. E. Barclay,

the post of junior radiologic officer to the Manchester Royal Infirmary. When Barclay, his chief, left Manchester for Cambridge, Twining succeeded him. He made great improvements in radiologic technic, devising more accurate and more economical methods. The original apparatus for tomography was almost prohibitively expensive, but he invented a simple attachment for enabling it to be carried out on any x-ray couch. His work on the radiography of the chest was monumental. This he embodied in the great new British work "A Textbook of X-Ray Diagnosis," which he edited in collaboration with Shanks and Kerley, of which two volumes have been published and a third is in preparation. Three fifths of the 500 pages of volume I are occupied with his work on the radiography of the chest, which is illustrated by 245 of his own roentgenograms and anatomic drawings. He was lecturer on radiology at Manchester University and had been chosen president of the Section of Radiology of the Royal Society of Medicine and of the Faculty of Radiologists.

PARIS

(From Our Regular Correspondent)

June 6, 1939.

Two Important Meetings

Two important meetings were held during the Whitsuntide vacations; one at Vittel on diuresis, the other at Spa, representing the international session on cardiology. The water exhibit was an added attraction to the Spa meeting. At Vittel, with Professor Rathery in the chair, some twenty papers were read. Mauriac and Saric of Bordeaux emphasized the morphologic factor in the tissular retention of water. Brull of Liège discussed the role of the endocrine system in the mechanism of diuresis. Govaerts and Lequime reviewed the output of the heart and its variations after the absorption of large quantities of water. These variations are not necessarily parallel to diuresis, since the latter is more considerable after the ingestion of a saline solution than after the ingestion of pure water. In order to account for the increase of the output and of the heart and that of diuresis, one must have recourse to the hypothesis of a certain degree of hydremia and of the dilatation of the viscera and the kidneys. Cornil and Malméjac of Marseilles, seeking to elucidate the part taken by the nervous system in diuresis or in the secretion of the kidney, arrived at the conclusion that one cannot assert the existence of secretory renal nerves but that the vasomotor variations of the kidney are a powerful factor in the quantity and quality of urinary discharge. From the therapeutic point of view the most noteworthy papers were those of Tiffeneau and of Mercier and Balansard, the one devoted to chemical, the other to vegetable, diuretics. Polonovsky described the work of the kidney in maintaining the basal equilibrium. Fiessinger presented a study of the stages in the passage of water during digestion, the metabolism of which is provided largely by extrarenal channels. The subject of Patel, Thevenot and Fontaine was the application of surgery to the treatment of oliguria. These papers and the discussions that accompanied them furnished a picture of what the French school thinks regarding diuresis.

The first of the Belgian sessions was devoted to the limitations of the electrocardiogram. In spite of the technical criticisms of Routier and the doubts raised by Van Dooren of the results offered by thoracic derivation, the speakers showed a tendency to show the justification of electrocardiography and of the methods derived from it rather than to restrict the field of its application. The next day, clinical proofs permitting the measurement of output of the heart were studied. The speakers endeavored to indicate how the movement of the heart can be measured at the bedside. The program for the third day dealt with coronary circulation and the myo-

cardium. This gave Régnier of Brussels and Boucomont of Royat an opportunity to discuss the consequences of the disorders of coronary circulation on the auricles and on the muscular tissue of the heart and the diagnostic means available to detect and analyze them.

Improvisation of a Floating Hospital

Dr. Armand, surgeon of the hospitals of Marseilles, described before the Academy of Medicine the manner in which a French packet, the *Marshal Lyautey*, served to hospitalize and treat a certain number of wounded Spaniards routed by the advance of Franco. This boat had a capacity of 10,500 tons and normally plied between France and Algeria. More than 1,500 wounded were received, almost all at the same time. There were as many as 1,200 persons aboard with only 1,080 beds. Five operating rooms were rapidly organized and five shifts of surgeons set to work. An x-ray division was added. Only about forty qualified nurses could be recruited. No physician nor any member of the Spanish military health service had accompanied the Spaniards to France. The volunteer services were much in demand in transporting, receiving, delousing, washing and clothing those who arrived and in securing for them some degree of comfort and health during their sojourn. Fortunately, though there was a shortage of personnel, the materials needed were superabundant. On the average, six major operations were performed daily and about a hundred dressings. Only eleven deaths occurred, none of which were caused by tetanus or postoperative infection. Nine of the deaths concerned men whose condition of health had been serious on their arrival. The vessel was disinfected daily with cresyl washings or by fumigation; bedding and clothes were steamed. A passenger boat quickly transformed into a hospital can clearly render good service. However, the narrowness of the passages and staircases was a source of annoyance, and sailors' berths did not lend themselves well to certain surgical needs.

Health Passbooks

The department of public health has just issued an order authorizing health passbooks (*carnets de santé*). These are to be complete, individual and confidential. Thus the results of the different tests which the French citizen takes throughout his life will be coordinated. These embrace all the phases of his life: nursing, schoolboy, applicant for civil or military positions, sports interests, army service, marriage, retirement, not to mention the examinations which he takes when he becomes ill, especially if he must undergo treatments of long duration. The practice of health examinations is spreading. In sickness it is absolutely necessary for the different physicians consulted to have before them the health record of their patient. It might be dangerous in certain cases not to be able to prove vaccination or serum treatment when the patient could have been given them. To secure all possible secrecy, the passbook will be anonymous and will bear only a number as well as the indication of the organization or physicians who first delivered it or who have added remarks.

Obituaries

Professor Nicolas, who succeeded Poirier as professor of anatomy in the Faculty of Medicine of Paris and who was the collaborator and subsequently the editor of his *Treatise on Anatomy*, died recently. Among other losses in the medical family are to be mentioned the death of Marcel Pinard, author of numerous studies on syphilis; that of Dr. Legrain, physician at the Seine asylum, who spent a long life in an ardent crusade against alcoholism, and of Prof. Marcel Labbé, whose researches on nutritional diseases and notably on diabetes were authoritative. He was a member of the Academy of Medicine.

BERLIN

(From Our Regular Correspondent)

May 31, 1939.

Medical and Social Care of Pernicious Anemia

Professor Dennig, director of the Moabit Hospital, one of the largest of Berlin's institutions for the sick and at the same time the fourth university medical clinic, recently discussed the question of pernicious anemia before the medical society of Berlin. The speaker stated that diagnosis in actual practice is either not made at all or is made too late, because many afflicted persons have no symptoms for a long time and then all of a sudden their hemoglobin content is found to be reduced below 30 per cent. The most frequent mistaken diagnoses are sepsis, inoperable carcinoma and infirmity of old age. According to the speaker's experiences, 50 per cent of those dismissed from the hospital as improved patients subsequently suffered a relapse and had to be rehospitalized. Relapses occur chiefly from six months to two years after release from the hospital. The chief causes of relapse are (1) change of physician combined with change in diagnosis, (2) insufficient instruction of the patient regarding further treatment after leaving the hospital, (3) termination of treatment by the physician and (4) economic difficulties; either the patients can no longer pay for the expensive liver preparations or the sick funds have completed their legally required contributions, while organizations of public welfare that usually begin to function in such cases decline to assume the high costs. The real reason for the frequency of relapses lies in the lack of adequate organization for treating patients continuously, as needed. In actual practice it is sufficient to determine the hemoglobin content and to prescribe liver preparations accordingly. He recommends especially injection of liver preparations. It is not only cheaper than oral administration but establishes a closer bond between patient and physician, necessary for regular control. Treatment with raw liver is expensive and unpleasant and is only occasionally employed as an additional measure. The number of injections depends on the condition of the patient and varies between once a day and once a month according to the condition of the patient and the effect of the preparation employed. Spinal disturbances cannot be improved although they do not grow worse, if the patient reports regularly for treatment.

Dr. Siebeck, professor of internal medicine in discussion, called attention to the fact that treatment of pernicious anemia should occur as early as possible, because myeloid symptoms are improvable in the initial stages. Prof. Werner Schultz, hematologist, emphasized the fact that many patients with this disorder attain old age with good treatment but develop gastric carcinomas. Professor Kalk, director of a section of a large Berlin hospital, recommended subsequent treatment with oral doses of gastric mucous membrane preparations. By means of the gastroscope often polypi can be recognized in the stomach of these patients. These polypi frequently become malignant. Pernicious anemia as well as these carcinomas arise secondarily to gastritis. If the patient recovers from pernicious anemia, there is great danger of further carcinomatous evolution.

Effect of Roentgen Rays on Tumor Cells

Hildegard Vollmar, in an address before the medical association of Tübingen, reported the effect of the roentgen rays on normal cells (embryonic tissues of chickens) and on tumor cells (mice carcinomas) recorded in a continuous film exposure. The peculiar value of the films consisted in the fact that not only could the final effect of radiation be shown but a continuous observation of the processes of irradiation was made possible. The experiment was so organized that, throughout, the same group of cells remained focused and exposed to the film. The x-ray tube set up at the side and focused on the cells allowed the rays to fall directly on them. Films were taken before, during and, at definite intervals of time, after the

irradiation. The dose consisted of 16 roentgens a minute at intervals of thirty, sixty, 120 and 180 minutes. In the case of normal cells, no radical impairment could be observed after an irradiation of thirty and sixty minutes; however, irradiation of 120 minutes (1,920 roentgens) revealed that within this time injury to the cells had set in, which continued and finally led to the death of the cells. The progress of this injury bore the following characteristics: (1) the motility of the cells gradually decreased; (2) the protoplasmic border surrounding the cells like a veil began to fold and shrink, the cell processes took on a spearlike form, the cell itself grew round, and (3) a small dose could destroy the cellular wall and allow the protoplasm to break through. The greater sensitiveness of the tumor cells to radiation was evidenced by the fact that irradiation of thirty minutes (480 roentgens) and of sixty minutes (960 roentgens) produced injury to the cells during irradiation. There was no recovery but the various phases of the injury terminated in the death of the cell. In irradiations of 120 and 180 minutes (1,920 and 2,880 roentgens) the cell died during the exposure. The same processes could be observed at first in tumor cells as in normal cells. A characteristic additional element was an intensive vacuolation under certain circumstances. Of special interest in the irradiation of the tumor cells was the great difference of their susceptibility to radiation. This could be clearly observed in the films. Often the individual cells of the same culture showed the greatest difference of susceptibility to radiation, so that some cells were not affected by even large doses or only to a much less degree. This observation can at once be interpreted according to the statistical theory of cell injury; that is, in the sense that a certain number of cells can escape the effects of radiation by sheer number. On the other hand, it may be a question of cells that escape injury by roentgen rays in their very nature; in other words, there may be a type of cell that is more or less ray resistant.

Electrocardiographic Peculiarities in the Course of Hyperthyroidism

Dr. Spang and Dr. Korth pointed out before the medical society of Berlin that a true picture of what takes place in the heart can be gained from observing the electrocardiographic changes during the course of hyperthyroidism. The condition of the heart can be read from the form of the terminal fluctuations. Most frequently after an operation, but also in cases of thyrotoxicosis, a change is found in the terminal fluctuation revealing a certain similarity to the "coronary T." This form of fluctuation is regarded as a specific indication of thyrotoxicosis and as the expression of a special reaction to the thyroid toxins which cannot be determined by other clinical methods of investigations. On the administration of digitalis a dissociation of symptoms becomes visible in the electrocardiogram: a slight effect on frequency and transition time though accompanied by a considerable change in terminal fluctuation. On viewing the electrocardiogram from right to left, one often discovers a typical change. Simultaneously with this change when the condition of thyrotoxicosis improves, e. g. after an operation, definite characteristic changes take place in the P wave and the roentgenogram. These changes in the form of the electrocardiogram and the roentgenogram attest a special power of the circulation peculiar to hyperthyroidism, an increase of resistance in the pulmonary circulation.

Death of Dr. Wagner, Medical Leader of the Reich

Dr. Wagner was 51 years old when he died. According to the official report he succumbed to an incurable malady; however, according to the German news bureau he died of a "treacherous disease which he had contracted in giving his services to the national socialistic movement." His position had been wholly insignificant until he joined the new political

movement. He assisted in founding the German society of physicians on the national socialistic basis and became its leader in 1932. In 1933 he was appointed reichsleader of the German physicians. In this capacity he had to deal authoritatively with all matters pertaining to physicians and in part also with problems that essentially concern research. He was a firm believer in national socialism and applied the deductions of this political theory to the general welfare. (Reports of these have appeared regularly in these columns.) Professor Reiter, president of the governmental bureau of health and himself a Nazi, speaks of him in an obituary as of "Gerhard Wagner, whom we national socialistic physicians called 'our father.'" He was given a state burial, attended by Hitler and a large retinue, with all the honors of the army and the political party.

ITALY

June 3, 1939.

International Radiomedical Department

The international radiomedical department situated in Rome recently ended its third year. Prof. Guido Guida, director, presented a report to the ministerial offices in which the work carried on in the course of 1938 for Italian and foreign sailors is given in detail. The department answered ninety-eight radio calls from ships. There were eighty-two clinical, seven surgical and nine accident cases. The physicians advised by radio that the patients be brought ashore immediately for operation. The orders were obeyed. The radio calls came from the Mediterranean in forty instances, from the Atlantic or Indian oceans in forty-eight and either from the Black Sea or from the North Sea in ten. By comparing the work done by the Roman department with that of other similar European centers it will be observed that England served, during 1938, twenty-nine radiomedical calls, France thirty, Holland thirty-seven, Finland fourteen, Ireland six and Belgium two. The most serious cases were those of epidemic influenza, bronchopneumonia, sunstroke, renal and hepatic colic pains, fractures and accidents injuring the eyes. Some grave cases developed on board steamers a few days away from port. In these instances they were advised by radio to approach any other steamer which was equipped with medical service. The department printed a small book of instructions and clinical records for distribution among the captains of ships.

Society Reunion

The Società Medica Coloniale met recently at Tripoli. Dr. Azzarello spoke on a meningo-encephalitic syndrome which he has observed in children who have had roentgen depilation in treatment of ringworm of the scalp. The symptoms last for about a month. The patients recover. The differential diagnosis is made with meningo-encephalitis and serous meningitis. A lively discussion followed the reading of Dr. Azzarello's article. Professor Bettòlo said that the speaker's report is of great interest as the symptoms indicate that the roentgen treatment may have caused acute or else a transient inflammatory reaction of the ventricular ependyma and of the choroidal plexus in persons with a predisposing constitution. He pointed out the advisability of following the behavior of the cerebrospinal fluid in the course of the disease. Professor Superbi believes that the meningeal reaction may show idiosyncrasy to roentgen irradiations. Professor Ciotola made reference by analogy to the inconveniences of the application of a helmet for permanent hair waving.

Personals

Prof. Giacinto Viola, head of the medical clinic of the University of Bologna, resigned recently on account of poor health. Professor Viola has been the pioneer in studies on individual constitution which have made an epoch in the history of the development of medicine. His method has found important

applications especially to biology and clinical medicine. Professor Viola has been the head of the medical clinics in various Italian universities. In the clinic of Bologna he organized a well equipped department for the application of this method of constitution to diagnostic research and also in relation to the application of the method to the treatment of diseases. He established a center for the specialization of physicians in physical therapy.

BUDAPEST

The Congress of Hungarian Sports Physicians

The Society of Home Defense Surgeons recently arranged the first Congress of Hungarian Sports Physicians, the aim of which was, first, to display the kind of work carried on by the home defense medical staff and to show how it contributed to the development of sports in home defense. The congress wanted also to document the great work which the ministry of home defense achieved by teaching home defense surgeons sports physician training and by purchasing equipment necessary to the sports physician. The congress was attended by representatives of the Hungarian universities and the Hungarian sports physician institutes and delegates of foreign universities and sports associations. The chief theme was the task of the sports physician with regard to sports and to the Olympic games of 1940.

The Budapest Center for Blood Donors

Dr. Kubányi, lecturer at the University of Budapest, issued a report on the function of the blood donor center at St. Rochus Hospital. Donors were required from October 1935, when the center was established, to December 1935 in twenty-eight cases, in 1936 in eighty-two cases, in 1937 in 172 cases and to Aug. 1, 1938, in 291 cases. A total of 158 donors are enrolled. During the three years a donor has not exceeded one hour in reporting after receiving the call. He is obliged to hand over his card, on which there is a column for noting whether he is punctual. Hospitals pay 30 pengös (about \$6) for each donation to regular ward patients, while for private paying patients the fee is higher. Donation of blood is not required from any donor oftener than eight times a year. In his report Dr. Kubányi suggests that, besides the establishing of blood groups and the Oehlecker biologic tests, the agglutination titer be fixed, lest an excessive difference exist between the titer of donor and patient.

Marriages

THOMAS DAVID DUBLIN, New York, to Miss Christina Macdonald Carlyle of West Roxbury, Mass., June 3.

ROBERT PEERS BUCKLEY, Duluth, Minn., to Miss Kate Wisdom Holland of Jackson, Tenn., May 16.

ERIC TWACHTMAN, Greenwich, Conn., to Miss Doris Walbridge Pinkham of New Canaan, June 3.

FRANCIS ASHLEY FAUGHT to Miss Elizabeth Hughes Mortimer, both of Philadelphia, May 15.

ELIZABETH B. WARD, Newark, N. J., to Mr. Frederick Lum Trowbridge of Chatham, May 20.

JAMES DONALD SMITH, Tuscaloosa, Ala., to Miss Gwendolyn Friegel in Montgomery in May.

ALLEN P. GURGANIOUS, Palatka, Fla., to Elizabeth Clark Hoster of New York, June 2.

ABRAM BIRD DANIEL, Statesboro, Ga., to Miss Dorothy Goolsby of Eastman, May 23.

L. FORREST SWANK to DR. LUCRETIA W. RICHISON, both of Elkhart, Ind., May 14.

WILLIAM HENRY KAUFMAN to Miss Beth Pearse, both of Durham, N. C., May 27.

Deaths

Edward Harris Goodman, Dorset, Vt.; University of Pennsylvania Department of Medicine, Philadelphia, 1902; at various times assistant instructor, instructor and associate in medicine at his alma mater; formerly associate professor of medicine at the Medico-Chirurgical College, Graduate School of Medicine, University of Pennsylvania; served in various capacities on the staffs of the University of Pennsylvania Hospital, Phipps Institute for Tuberculosis, Philadelphia General Hospital and Presbyterian Hospital, Philadelphia, Children's Sea Shore House, Atlantic City, N. J., and the White Haven (Pa.) Sanatorium; secretary of the American committee of the International Congress in Budapest in 1909; served during the World War; author of "Blood Pressure in Medicine and Surgery" published in 1914; aged 59; died in March in a hospital at Philadelphia.

Frank Stiles Owen, Santa Barbara, Calif.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1885; member of the American Academy of Ophthalmology and Oto-Laryngology; fellow of the American College of Surgeons; professor emeritus of laryngology and rhinology at the University of Nebraska College of Medicine; past president of the Omaha-Douglas County Medical Society and the Nebraska State Medical Association; formerly oculist and aurist to the Immanuel Deaconess Institute and St. Catherine's Hospital and rhinologist and laryngologist to the University Hospital, Omaha; aged 82; died, March 23, of carcinoma of the prostate, arteriosclerosis and uremia.

Joseph Edgar Stewart, St. Louis; University of Pennsylvania School of Medicine, Philadelphia, 1914; instructor in clinical orthopedic surgery, Washington University School of Medicine; member of the American Orthopedic Association, Clinical Orthopedic Society and the American Academy of Orthopedic Surgeons; served during the World War; at various times and capacities on the staffs of the Barnes Hospital, St. Louis Children's Hospital, St. Louis Maternity Hospital and St. Louis City Hospital; aged 48; died, March 5, of coronary thrombosis.

Gilbert Molleson Elliott, Brunswick, Maine; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1889; member of the Maine Medical Association; veteran of the Spanish-American and World wars; for many years member of the school committee, and member of the board of health; formerly on the staff of the Brunswick Hospital; aged 71; died, March 31, in a hospital at Brattleboro, Vt.

Thomas Lowe, Pipestone, Minn.; Hahnemann Medical College and Hospital, Chicago, 1885; past president of the Minnesota State Board of Medical Examiners; formerly mayor of Pipestone; past president of the Southwestern Minnesota Medical Society; member of the state legislature; on the staff of the Ashton Memorial Hospital; aged 80; died, March 12, in the West Side General Hospital, St. Paul, of pneumonia.

Charles Simpson Woodall, Brandon, Vt.; Harvard University Medical School, Boston, 1924; member of the American Psychiatric Association and the New England Society of Psychiatry; superintendent of the Brandon State School for the Feeble-minded; at one time assistant superintendent of the Walter E. Fernald State School, Waverly, Mass.; served during the World War; aged 45; died, March 26, of angina pectoris.

Albert Louis Voltz, Richmond Hill, N. Y.; Long Island College Hospital, Brooklyn, 1908; member of the Radiological Society of North America; past president of the Medical Society of Queens County; on the staffs of the Jamaica (N. Y.) Hospital, Lutheran Hospital, Brooklyn, and the Creedmoor State Hospital, Queens Village; aged 55; died, March 27, in the New York Hospital of heart disease.

George Tucker Smith, Medical Director, Rear Admiral, U. S. Navy, retired, Charlottesville, Va.; University of Virginia Department of Medicine, Charlottesville, 1888; entered the navy in 1889 and retired in 1929 on his own application after forty years' service; fellow of the American College of Surgeons; aged 72; died, March 18, in the University of Virginia Hospital, of lobar pneumonia.

Conrad Georg, Ann Arbor, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1899; member of the American Association for Thoracic Surgery; served during the World War; at one time second assistant

in surgery and demonstrator at his alma mater; aged 64; died, April 15, of an incised wound of the throat and wrist, self inflicted with a scalpel.

Buenaventura H. Portuondo, Belleville, Ill.; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1889; past president and secretary of St. Clair County Medical Society; formerly chairman of the board of health of Belleville; on the staff of St. Elizabeth's Hospital; aged 73; died, March 9, in St. Anthony's Hospital, St. Louis, of pneumonia.

Eli Moores Watts, Texarkana, Texas; Tulane University of Louisiana School of Medicine, New Orleans, 1909; past president and secretary of the Bowie County Medical Society; on the staff of the Texarkana Hospital; for many years member of the board of education; formerly health officer; aged 54; died, March 28, of heart disease.

William H. Zwickey, Superior, Wis.; Wisconsin College of Physicians and Surgeons, Milwaukee, 1906; also a pharmacist; past president of the Douglas County Medical Society; physician in charge of the Douglas County Asylum Home and Sanatorium, Itasca; aged 69; died, March 17, in St. Francis Hospital of chronic pulmonary tuberculosis.

Henry Hurlburt Tomlin, Wildwood, N. J.; University of Pennsylvania Department of Medicine, Philadelphia, 1905; president of the Cape May County Medical Society; served during the World War; school physician; aged 62; died, March 10, of coronary occlusion while aboard ship during a South American vacation cruise.

Thomas Albert Starkey, Montreal, Que., Canada; L.R.C.P., London, M.R.C.S., England, 1894; University of London Faculty of Medicine, London, England, 1895; formerly Strathcona professor of hygiene at McGill University Faculty of Medicine; served during the World War; aged 67; died in March at Claremont, Jamaica, B. W. I.

Lex Glin McCutchen, St. Louis; St. Louis University School of Medicine, 1924; senior instructor in radiology at his alma mater; member of the Radiological Society of North America; aged 44; on the staff of the Firmin Desloge Hospital, where he died, March 31, of coronary occlusion and arteriosclerosis.

Frank Embery, Philadelphia; Medico-Chirurgical College of Philadelphia, 1892; member of the American Academy of Ophthalmology and Oto-Laryngology; fellow of the American College of Surgeons; on the staff of the Frankford Hospital; aged 72; died, March 17, at his summer home in Southampton.

Charles Schultz, New York; McGill University Faculty of Medicine, Montreal, Que., Canada, 1923; member of the Medical Society of the State of New York; psychiatrist of the city department of hospitals; aged 40; died, March 24, in Detroit of self-inflicted stab wounds and an overdose of a narcotic, self administered.

Glenwood Medcalfe De Lisser, Tupper Lake, N. Y.; Washington University School of Medicine, St. Louis, 1897; member of the Medical Society of the State of New York; on the staffs of the Mercy General Hospital and the American Legion Mountain Camp; aged 65; died, March 7, of bronchopneumonia.

Byron William Shaw, Waunakee, Wis.; Cleveland College of Physicians and Surgeons, Medical Department of Ohio Wesleyan University, Cleveland, 1898; member of the State Medical Society of Wisconsin; aged 67; died, March 15, in St. Mary's Hospital, Madison, of coronary thrombosis.

John Henry Reed, Logansport, Ind.; University of Maryland School of Medicine, Baltimore, 1885; member of the Indiana State Medical Association; aged 78; on the staffs of the Cass County Hospital and St. Joseph's Hospital, where he died, March 2, of pneumonia.

Robert Raymond Sellers, Newark, N. J.; Medical College of the State of South Carolina, Charleston, 1914; served during the World War; on the staff of the Hospital of St. Barnabas and for Women and Children; aged 52; died, March 13, of coronary occlusion.

Helene Piutti, Freiburg, Germany; Albert-Ludwigs-Universität Medizinische Fakultät, Freiburg, Baden, Germany, 1922; formerly on the staff of the State Hospital for Mental Diseases, Howard, R. I.; aged 45; died, March 4, in an automobile accident.

Lettie Allen Ward, Camden, N. J.; Woman's Medical College of Pennsylvania, Philadelphia, 1898; member of the Medical Society of New Jersey; aged 80; died, March 18, in the Cooper Hospital of bronchopneumonia and arteriosclerotic heart disease.

Frank E. O'Neil Prescott, Kan.; University Medical College of Kansas City, Mo., 1895; member of the Kansas Medical Society; past president of the Linn County Medical Society; aged 69; died, March 20, in a hospital at Fort Scott of lobar pneumonia.

Harold Phillips Shepard, Newark, N. J.; Hahnemann Medical College and Hospital of Philadelphia, 1938; aged 27; intern at the Hospital of St. Barnabas and for Women and Children, where he died, March 25, of acute lymphatic leukemia.

Thomas Simpson Kennedy, Fort Lauderdale, Fla.; University of the South Medical Department, Sewanee, Tenn., 1901; veteran of the Spanish-American War; aged 80; died, March 28, of carcinoma of the right side of the neck.

Russell Clinton McNeill & Kenton, Ohio; Starling Medical College, Columbus, 1896; past president of the Hardin County Medical Society; on the staff of the McKittrick Hospital; aged 69; died, March 9, of coronary occlusion.

James Thomas Smith, Westfield, N. C.; North Carolina Medical College, Davidson, 1898; formerly a minister; aged 61; died, March 14, in the Martin Memorial Hospital, Mount Airy, of aplastic anemia and ischio-rectal abscess.

Claude Benjamin Mills & Cross Hill, S. C.; Medical College of the State of South Carolina, Charleston, 1913; served during the World War; aged 50; died, March 1, in the Veterans Administration Facility, Columbia.

John Alsop Pilcher Jr. & Roanoke, Va.; University of Virginia Department of Medicine, Charlottesville, 1929; on the staff of the Gill Memorial Eye, Ear and Throat Hospital; aged 34; died, March 7, of a gunshot wound.

Anna M. Hill Shinnick, Zanesville, Ohio; Woman's Medical College of Cincinnati, 1894; aged 75; died, March 12, in the Mount Carmel Hospital, Columbus, of arteriosclerosis, diabetes mellitus and cerebral hemorrhage.

Roy Hamilton Peck, Springfield, Mass.; Kentucky School of Medicine, Louisville, 1903; member of the Massachusetts Medical Society and the American Urological Association; aged 58; died, March 29, of carcinoma.

Alonzo L. Lawson, Elk Valley, Tenn.; Hospital College of Medicine, Louisville, Ky., 1896; member of the Tennessee State Medical Association; member of the county board of education; aged 66; died, March 10.

Frank Stephen Skinner & Marion, Iowa; Rush Medical College, Chicago, 1897; past president of the Linn County Medical Society; aged 66; died, March 7, of chronic myocarditis and auricular fibrillation.

Edwin D. Merritt, Detroit; Detroit College of Medicine, 1899; member of the Michigan State Medical Society; on the auxiliary staff of the Grace Hospital; aged 68; died, March 23, of coronary thrombosis.

Wilfred H. Schuyler, Boise, Idaho; College of Physicians and Surgeons of Chicago, 1883; member of the Idaho State Medical Association; aged 80; died, March 10, in the Veterans Administration Facility.

Charles V. Steward, Bolivar, Mo.; Missouri Medical College, St. Louis, 1886; member of the Missouri State Medical Association; aged 81; died, March 11, in the Pinal County Hospital, Florence, Ariz.

Charles Albert Weaver & Manchester, N. H.; University of Vermont College of Medicine, Burlington, 1881; director, venereal disease control, state board of health; aged 83; died, March 5.

Louis Wesley Soland, Denver; Denver and Gross College of Medicine, 1910; served during the World War; aged 54; died, March 16, in St. Luke's Hospital of an overdose of a narcotic.

Harry Creighton Pepper, Orleans, Ind.; Indiana University School of Medicine, Indianapolis, 1933; member of the Indiana State Medical Association; aged 33; died, March 6, of gunshot wounds.

Arthur Edwin Osmond, Cincinnati; Medical College of Ohio, Cincinnati, 1904; served during the World War; aged 61; died, March 10, of a posterior lateral sclerosis of the spine.

Frank Rudolph Silver, Harwich Port, Mass.; Harvard University Medical School, Boston, 1903; aged 67; died, March 18, in the Cape Cod Hospital, Hyannis, of aneurysm of the aorta.

George Wellington Frasier, Bear Valley, Calif.; University of Minnesota College of Medicine and Surgery, Minneapolis, 1905; aged 62; died, March 27, of chronic myocarditis.

Elbert George Payne, Spokane, Wash.; Michigan College of Medicine and Surgery, Detroit, 1905; aged 75; died, March 9, in the Sacred Heart Hospital of cerebral hemorrhage.

Paul Gageby, Barberton, Ohio; Northwestern University Medical School, Chicago, 1927; fellow of the American College of Surgeons; aged 38; died, April 15, of tumor of the pons.

Edwin William Bathurst & Etna, Calif.; Medical College of the Pacific, San Francisco, 1877; aged 84; died, March 8, of cardiovascular renal disease and hypostatic pneumonia.

Doran Therman Rue, Mattoon, Ill.; University of Illinois College of Medicine, Chicago, 1932; aged 32; was found dead, March 31, of an overdose of a drug, self administered.

Frederick F. Quilliams, Cleveland; Cleveland Medical College, 1897; aged 68; on the staff of the Huron Road Hospital, where he died, March 9, of diabetes mellitus.

Henry C. Peckham, Freeport, Mich. (licensed in Michigan in 1900); Civil War veteran; aged 93; died, March 12, of hypostatic pneumonia following an attack of influenza.

Jacob Swigert Coleman & Frankfort, Ky.; Hospital College of Medicine, Louisville, 1876; aged 83; on the staff of the King's Daughters' Hospital, where he died, March 26.

Charles Francis Kueny, Beverly Hills, Calif.; State University of Iowa College of Medicine, Iowa City, 1887; aged 77; died, March 21, of carcinoma of the stomach.

John Albert Penner, Detroit; University of Toronto Faculty of Medicine, Toronto, Ont., Canada, 1931; aged 42; died suddenly, March 14, of coronary thrombosis.

Fletcher Eugene Lee, Columbus, Miss.; University of Tennessee Medical Department, Nashville, 1904; aged 65; died, March 20, of acute yellow atrophy of the liver.

Frank James Neifer, South Bend, Ind.; Eclectic Medical Institute, Cincinnati, 1884; aged 79; died, March 11, in the Epworth Hospital of abdominal carcinomatosis.

Lesley Edwin Wallace, Thebes, Ill.; University of Louisville (Ky.) School of Medicine, 1922; aged 42; died, March 20, of an overdose of a hypnotic, self administered.

Egerton Ferguson Card, San Francisco; Cooper Medical College, San Francisco, 1885; aged 85; died, March 1, of coronary artery disease and pulmonary infarction.

Charles Harney George, Willowbrook, Calif.; Jefferson Medical College of Philadelphia, 1908; aged 72; died, March 22, of cerebral hemorrhage and arteriosclerosis.

Wallace Peter MacCallum, Belmont, Mass.; Jefferson Medical College of Philadelphia, 1904; aged 60; died, March 9, in East Boston of coronary heart disease.

Rolland Wilton Halladay, Toronto, Ont., Canada; Queen's University Faculty of Medicine, Kingston, 1905; served during the World War; aged 57; died, March 22.

Laura C. Brickley Knapp, Palms, Calif.; Pulte Medical College, Cincinnati, 1885; aged 83; died, March 1, of hypertension and arteriosclerotic heart disease.

William Edward Philes, Washington, D. C.; National University Medical Department, Washington, 1901; aged 73; died, March 19, of heart disease.

Elmer Hezekiah Sothoron, Washington, D. C.; Bellevue Hospital Medical College, New York, 1890; aged 70; died, March 11, of chronic myocarditis.

Devillo P. Simons, Udall, Kan.; College of Physicians and Surgeons, Keokuk, Iowa, 1888; aged 79; died, March 25, of malignancy of the prostate.

William Bond Snipes, Aubrey, Ark.; Vanderbilt University School of Medicine, Nashville, Tenn., 1888; aged 79; died in March of arteriosclerosis.

Donald McLennan, Plattsville, Ont., Canada; McGill University Faculty of Medicine, Montreal, Que., Canada, 1888; aged 76; died, March 26.

James Berry Rickman, Rutherford, Tenn.; Vanderbilt University School of Medicine, Nashville, 1892; aged 76; died, March 7, of pneumonia.

William Painter, University Park, Iowa; Rush Medical College, Chicago, 1881; aged 82; died, March 30, in Dubuque of cerebral hemorrhage.

Edward Andrew Hanna, Los Angeles; Chicago Medical College, 1886; aged 74; died, March 26, of cerebral hemorrhage.

Val F. Seel, Walnut Ridge, Ark. (licensed in Arkansas in 1903); aged 81; died, March 22, of bronchopneumonia.

Plesant A. Ogle, Crawford, Tenn. (licensed in Tennessee in 1907); aged 67; died, March 15, of heart disease.

Bureau of Investigation

MISBRANDED "PATENT MEDICINES"

Abstracts of Notices of Judgment Issued by the Food and Drug Administration of the United States Department of Agriculture

[EDITORIAL NOTE.—The abstracts that follow are given in the briefest possible form: (1) the name of the product; (2) the name of the manufacturer, shipper or consigner; (3) the composition; (4) the type of nostrum; (5) the reason for the charge of misbranding, and (6) the date of issuance of the Notice of Judgment—which is considerably later than the date of the seizure of the product and somewhat later than the conclusion of the case by the Food and Drug Administration.]

Bewino Beef Wine and Iron Tonic and Builder.—Lucky Heart Laboratories, Inc., Memphis. Composition: Essentially a small amount of iron and ammonium citrate, protein, sugar, alcohol and water. Fraudulently represented as a "tonic," blood purifier, etc.—[N. J. 28311; September 1938.]

Butler's Cod Liver Oil Ointment.—Anedemin Chemical Co., Chattanooga. Composition: Essentially petrolatum and fish oil. Fraudulently represented as a remedy for burns, wounds, ulcers, etc.—[N. J. 28353; September 1938.]

Erbru Health Herbs and Iron.—Lucky Heart Laboratories, Inc., Memphis. Composition: Essentially epsom salt, a small amount of an iron compound, and extracts of plant drugs including a laxative, with salicylates, sugar and water. Fraudulently represented as a remedy for kidney, stomach, blood and nerve disorders.—[N. J. 28311; September 1938.]

Fairey's Famous Long Life Liquid.—Fairey Wholesale Drug Co., Orangeburg, S. C. Composition: A water-glycerin solution of plant extracts, including emodin-bearing drugs and a small amount of sodium benzoate. For indigestion, bad breath, headache, kidney, bladder and blood disorders, etc. Fraudulent therapeutic claims.—[N. J. 28329; September 1938.]

Formula 281.—Isabella Laboratories, Chicago. Composition: Tablets containing dinitrocresol and phenolphthalein; samples examined contained from 0.32 grain to 0.46 grain of the former, and 0.25 grain to 0.29 grain of the latter, per tablet. Fraudulently represented as reducing weight without endangering the health, when used as directed.—[N. J. 28339; September 1938.]

Four Star One Night Healing Salve.—Leone Perfumers Keystone Laboratories, Memphis. Composition: Essentially menthol, eucalyptol, wintergreen and camphor, in petrolatum. Fraudulently represented as a remedy for pneumonia, influenza, all skin infections, etc.—[N. J. 28342; September 1938.]

Gall-Flo.—Gall-Flo Laboratories, Inc., Cleveland. Composition: Essentially water, alcohol, plant extracts, and an unidentified alkaloid. Fraudulently represented as a remedy for gallbladder and certain stomach disorders, antacid irritability, etc.—[N. J. 28319; September 1938.]

Gold Medal Cold Capsules, Alpha Cold Capsules, and Gray's Cold Capsules.—Although these bore different firm names (respectively, S. Pfeiffer Mfg. Co., Virginia Chemical Co. and Gray Pharmaceutical Co., all of St. Louis), the three nostrums were believed to be one and the same thing, and a specimen of each product was found to contain 1.79 grains of acetanilid, whereas each package claimed that the capsules contained 1½ grains of this substance, and hence the labeling was false and misleading.—[N. J. 28340; September 1938.]

Horsford's Acid Phosphate.—Rumford Chemical Works, Providence. Composition: Essentially water; phosphoric acid, and the acid phosphates of calcium, magnesium, sodium, potassium and iron, with 500 parts per million of fluorine. Adulterated in containing an added poisonous or deleterious ingredient, fluorine, and misbranded because falsely represented as a remedy for physical exhaustion, headaches, stomach disorders, etc.—[N. J. 28346; September 1938.]

Lawrence Caustic Balsam.—Lawrence-Williams Co., Cleveland. Composition: Chiefly a saponified oil, a terpene oil, and cantharides. Fraudulently represented to relieve pains, open or raw flesh, and strengthen the muscles.—[N. J. 28323; September 1938.]

Lee's Prescription for Hay Fever and Asthma.—Erie Laboratories, Cleveland. Composition: Chiefly acetylsalicylic acid, phenacetin and a small amount of an unnamed alkaloid. Fraudulent therapeutic claims.—[N. J. 28368; September 1938.]

Lucky Heart Wonder Skin Ointment and Brightener.—Lucky Heart Laboratories, Inc., Memphis. Composition: A small amount of red mercuric oxide (2.8 per cent), incorporated in a petrolatum base. For mercuric oxide (2.8 per cent), incorporated in a petrolatum base. For removing skin blemishes, such as eczema, pimples, ringworm, tetter, sallowness, etc. Fraudulent therapeutic claims.—[N. J. 28311; September 1938.]

Minto-San Mint Formaldehyde Spray.—Huntington Laboratories of Colorado, Inc., Denver. Composition: Essentially formaldehyde, soap, oil of spearmint, water and green coloring. Fraudulently represented as a remedy for bacteriological disturbances.—[N. J. 28328; September 1938.]

Midland Hospital Germolyptus.—Midland Chemical Laboratories, Inc., Dubuque, Iowa. Composition not given. Misbranded because the alcohol content was not stated on the label and because the product was falsely represented to be a germicide, disinfectant and antiseptic, when used as directed.—[N. J. 28330; September 1938.]

Organic Sea Food.—Organic Sea Products Corp., San Francisco. Composition: Essentially coarsely ground seaweed, with a very small amount of agar. Fraudulently represented to give vitality and eliminate poisons, cure deficiency diseases and conditions such as rheumatism, asthma, goiter, anemia, catarrh, etc., and prevent insanity, baldness and wrinkles.—[N. J. 28314; September 1938.]

Parker's (Dr.) Tablets.—Dr. Parker Medicine Co., Chicago. Composition: Extracts of plant drugs, including nux vomica and resinous material, with a small amount of phosphides. For sluggish kidneys, torpid liver, nervous debility, insomnia, impotency, etc. Fraudulent therapeutic claims.—[N. J. 28350; September 1938.]

Pinolator Treatment.—Pinolator Co., Minneapolis. Composition: A liquid containing essentially small proportions of thymol, benzoic acid and volatile oils including pine-needle and peppermint oils and camphor, acetone and a green dye. Fraudulently represented as a remedy for sinusitis, asthma, pneumonia, tonsillitis, etc.—[N. J. 28338; September 1938.]

Pneumo Oil.—Pneumo Oil Co., Detroit. Composition: Essentially kerosene, oil of peppermint and a small amount of camphor. Misbranded because of claim, "Alcohol 10 per cent," whereas no alcohol was found; fraudulently represented as a relief in pneumonia, tonsillitis, rheumatism, influenza, etc.—[N. J. 28322; September 1938.]

Protex.—Tex Products Co., Wheeling, W. Va. Composition: Essentially a small amount of a chlorine-liberating product in an effervescent base. Fraudulently represented as a remedy for vaginal inflammation or discharge, burning urine, periodic headaches, lack of sexual desire, etc.—[N. J. 28363; September 1938.]

Puritan Brand General Tonic.—Clyde Collins Chemical Co., Memphis. Composition: Essentially epsom salt, small amounts of sodium citrate, extracts of plant drugs, saccharin, salicylic acid, an iron compound and water. For kidney, bladder, stomach and sexual ailments. Fraudulent therapeutic claims.—[N. J. 28321; September 1938.]

Puritan Brand Liniment.—Clyde Collins Chemical Co., Memphis. Composition: Essentially light petroleum oil containing small amounts of eucalyptol and wintergreen, colored with red dye. Fraudulent therapeutic claims.—[N. J. 28321; September 1938.]

Puritan Brand Treatment Tablets.—Clyde Collins Chemical Co., Memphis. Composition: Iron oxide, small amounts of zinc phosphide and strychnine, with milk sugar, talc and a gum. For sexual debility. Fraudulent therapeutic claims.—[N. J. 28321; September 1938.]

V-T Preparation.—V-T Laboratories, Inc., and W. D. Taylor & Co., Bessemer, Ala. Composition: Essentially plant drugs including a laxative, with small quantities of potassium iodide and sodium salicylate, plus alcohol, sugar and water. Fraudulently represented to prevent or cure beriberi and pellagra, to cure stomach bloating, restore appetite, etc.—[N. J. 28344; September 1938.]

Vapo Nose and Throat Drops.—Lucky Heart Laboratories, Inc., Memphis. Composition: Essentially small proportions of ephedrine, eucalyptol and cinnamic aldehyde, in a mineral oil base. Fraudulent therapeutic claims.—[N. J. 28311; September 1938.]

Vapo Overnight Salve.—Lucky Heart Laboratories, Inc., Memphis. Composition: Approximately 10 per cent of volatile oils including menthol, eucalyptol and wintergreen, in a petrolatum base. For coughs, sore throats, tonsillitis, asthma, neuralgia, backache, rheumatism, "piles," etc. Fraudulent therapeutic claims.—[N. J. 28311; September 1938.]

San-I-Gene Douche Powder.—Lucky Heart Laboratories, Inc., Memphis. Composition: Essentially boric acid (90 per cent), and small amounts of paraformaldehyde, potassium alum and wintergreen, perfumed with peppermint. Not antiseptic when used as directed. Fraudulent therapeutic claims.—[N. J. 28311; September 1938.]

Tiger Head Antiseptic Nerve and Bone Liniment.—Lucky Heart Laboratories, Inc., Memphis. Composition: Essentially extracts of plant drugs including red pepper, a small amount of oil of sassafras, and alcohol (about 58 per cent by volume), with chloroform (about 23 minims per fluidounce), and water. Fraudulently represented to cure diseases or disorders of the nerves and bones, relieve pains and cramps, cuts, burns, neuralgia, etc.—[N. J. 28311; September 1938.]

Ward's (Dr. J. R. W.) Formulas.—Standardized Remedies, Inc., New York. Composition: "Formula No. 448" (for hardening of arteries), plant material including blessed thistle, and probably licorice; "No. 444" (for dropsy), coarsely ground plant material including camomile flowers, cotton-root bark, and probably dog grass, senna and podophyllum; "No. 447" (for high blood pressure), plant material including probably camomile, podophyllum and kamala; "No. 434" (for diabetes), plant material including camomile flowers, lovage root and probably cotton-root bark, dandelion, and podophyllum; "No. 459" (for weakness of the heart), plant material including podophyllum root and starch, and other plant tissues not recognized. Fraudulent therapeutic claims.—[N. J. 28320; September 1938.]

Correspondence

FUNGUS INFECTIONS TREATED BY IONTOPHORESIS OF COPPER

To the Editor:—The communication of Dr. George Lewis, New York (THE JOURNAL, May 6, p. 1851), is of interest because of the direction from which Dr. Lewis approaches the question. Dr. Lewis is a trained and competent mycologist. From that point of view he criticizes the article on "Fungous Infections of the Hands and Feet Treated by Iontophoresis of Copper" by Haggard, Greenberg and myself.

We have deliberately approached the problem from the point of view of the average dermatologist and the general practitioner. Dr. Lewis possibly makes exact mycologic diagnoses in all his cases. The average dermatologist does not do this. He does not because, to quote from Dr. Lewis's own writing, "laboratory methods for the detection and identification of fungi pathogenic to man are time consuming and sometimes difficult to carry out, and the results are frequently inconclusive" (*Arch. Dermat. & Syph.* 38:713 [Nov.] 1938). Therefore I feel that we were justified in basing our diagnoses on the same criteria that are generally used in making a diagnosis of ringworm of the feet and hands.

The comparison to pneumonia is, in my opinion, not pertinent. In pneumonia a careful bacteriologic diagnosis is important since the therapeutic methods are dictated by the invading organism. While it must be admitted that there is a wide variation in response to treatment of the superficial fungous diseases according to species of infecting micro-organism, we have not yet, despite the valiant efforts of the mycologists, reached the point where we can say that one fungus is vulnerable to one form of medication and another to a different form.

Although he does not so state directly, Dr. Lewis implies that ringworm of the hands and feet is easily controlled with the exception of those cases caused by *Trichophyton purpureum*. If this is true, infection with that micro-organism must be common. It has been my experience that one of the most difficult problems with which dermatologists have to cope is the control of fungous infections of the hands and feet; and I have no reason to believe that my experience is unique. In the article quoted, Dr. Lewis himself states that "cure of most fungous diseases is rare."

Dr. Lewis suggests that the use of the trichophytin reaction would have been of assistance. In this he is doubtless quite correct. However, he must admit that, if the specificity of this reaction had been definitely established beforehand, he himself would not have carried out the long series of experiments reported in his paper as mentioned. Admitting that he and his co-workers have established this test as simple and specific, it must be remembered that the results of this work were published subsequent to the time when our experiments were carried out and our paper was submitted for publication.

Dr. Lewis asks one definite question and makes, by implication, one accusation. Both require answers. The observations were reported as a preliminary report because the clinical results were so impressive that it seemed worth while to allow other workers to use this method. Perhaps Dr. Lewis himself, with the great amount of clinical material at his command, can give this method a thorough trial. As for the implication that we have misquoted Dr. Downing and his collaborators, we must enter a plea of not guilty. Dr. Downing quotes the finding by other workers of pathogenic fungi on a small percentage of apparently normal skins and comments on the fact that although the percentage is small, nevertheless his own results agree with those of the other workers. We did not state that pathogenic fungi are found on normal skins with any regularity but only that they may be found.

Dr. Lewis possibly feels that he is traveling the high road of laboratory controlled investigations and that we are traveling

the low road of clinical observation, but there is no question that we are all striving to reach the same destination; that is, the finding of a method by which we can successfully and completely relieve the symptoms caused by infection of the hands and feet by fungi. From the patient's point of view, relief obtained is not measured in terms of mycology. He judges results by freedom from symptoms—clinical results.

We make no claim to having discovered anything new. We have simply used a chemical which has been used before with the aid of a physical technic which has also been used before. By persisting in the use of these, we believe that we have with our technic accomplished a fair percentage of clinical cures.

MAURICE J. STRAUSS, M.D., New Haven, Conn.

ANGINA PECTORIS WITH DIAPHRAGMATIC FLUTTER

To the Editor:—Readers may still be interested to hear that the patient with symptoms of angina pectoris whose diaphragmatic flutter has attracted much attention has put in his appearance on the West Coast.

He was brought by ambulance to the Collis P. and Howard Huntington Memorial Hospital, Pasadena, Calif., April 1, exhibiting his well known and oft repeated symptoms of severe pain in the chest and down the left arm. His pulse was 84 and the blood pressure 130 systolic, 75 diastolic. Examination of the chest revealed normal heart tones but a peculiar swishing, oscillation of about 300 per minute. He gave his name as Frank Crowley, his age as 65, and his occupation as a deep sea diver. He feigned some reluctance to taking morphine, and as soon as it had been given became very verbose as to the work he had done, ranging from such minor diving assignments as work on the Holland tube and San Francisco bridges to really heroic work such as the time when he, single handed, was responsible for the raising of two United States submarines, for which work he claims to have been given a congressional medal. He cited the article of Dr. W. B. Porter in THE JOURNAL, March 21, 1936, page 992. He seemed greatly pleased at the suggestion of his case being presented at a staff meeting two days later. During that time he was very cooperative and cleverly did not request morphine except by subtle means. Nothing abnormal was found electrocardiographically and diaphragmatic flutter and paralysis of the left diaphragm were seen fluoroscopically. Laboratory tests revealed nothing except a carbon dioxide content of 84 volumes per cent. Interest in the case was heightened by the article by Whitehead, Burnett and Lagen in THE JOURNAL, April 1, which reached our hands on the exact day of the staff meeting. The patient became angered when one of the doctors recognized him at the meeting and he was morose and sullen from that time on. Because the social workers were investigating his case it was thought advisable to transfer him to the Los Angeles General Hospital. The disposal of his case is not known to me.

OWEN A. KEARNS, M.D., Pasadena, Calif.

Intern, Huntington Memorial Hospital.

TREATMENT OF EDEMA

To the Editor:—Concerning Dr. Milhorat's discussion (Treatment of Edema, THE JOURNAL, March 4, p. 837), I would call attention to a therapeutic trick which can be used when extravasation outside the vein occurs when mersalyl (salyrgan) is injected intravenously. If one promptly injects the contents of one ampule of sodium cacodylate (three fourths grain [0.05 Gm.] to the cubic centimeter into and about the extravasation, no pain, necrosis or slough ensues. Salyrgan may also be combined with sodium cacodylate (an ampule of each) for giving painless intramuscular injections. I have given salyrgan and sodium cacodylate together subcutaneously with good results.

M. B. MARKS, M.D., Miami Beach, Fla.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

FREQUENCY OF URINATION

To the Editor:—A married woman aged 36, the mother of two children, the youngest aged 9 years, has had frequency of urination for the past year following the death of her father. The frequency is present day and night and is worse when she is riding in an automobile and when she is worried. Physically she is underweight; she has had a thyroidectomy and an appendectomy. The heart and lungs are normal, both kidneys are palpable and there is a moderate retroversion of the uterus. Examination of the blood gives negative results; the urine shows no abnormalities. A pyelogram of the kidneys and ureter show both kidneys low and the ureter kinked and dilated. I have tried various urinary sedatives with no effect. On the advice of a specialist I got an abdominal support, but so far without any effect on the frequency. Could you suggest anything further? Is it possible for the proptosed kidneys to be the cause of the frequency? Could the retroverted uterus be the cause? How successful are operative procedures in curing this condition?

M.D., Iowa.

ANSWER:—The first thing that this patient needs is a complete physical examination, to be followed by a complete urologic examination including a cystoscopic examination and careful bacteriologic studies of the urine to rule out the possibility of tuberculosis. This should include not only smears of catheterized specimens but cultures for tuberculosis as well as guinea pig inoculations. From the history, one might be inclined to attribute the frequency of urination to the death of her father. In other words, one might be able to explain the frequency on a nervous basis. On the other hand, patients who have nervous polyuria, or frequency on a nervous basis, have it in the daytime and, as a rule, do not have frequency at night. The fact that this patient is obliged to pass urine at night also makes one suspicious of organic disease, such as chronic nephritis, some form of diabetes or renal tuberculosis. It may be possible too that the frequency is due to the retroversion of the uterus. The simplest way to rule out this possibility would be to correct the malposition of the uterus by inserting a pessary, to see what happens. This is a relatively simple procedure and might answer the question. It is not at all likely that the ptosed kidneys are the cause of the frequency. Not knowing the cause of the frequency, one is not justified in answering the question as to how successful operative procedures are in curing this condition. One hardly knows what operation to recommend.

HYPERTENSION AND PULMONARY TUBERCULOSIS

To the Editor:—How often are pulmonary tuberculosis and essential hypertension associated? References to the subject will be appreciated.

M.D., North Carolina.

ANSWER:—Essential hypertension is less frequent in patients with pulmonary tuberculosis than it is in the usual population. Bunta (Blood Pressure Variations in Tuberculosis, *Am. Rev. Tuberc.* 29:335 [March] 1934) found no hypertension in 504 cases of pulmonary tuberculosis, and Ayman (Arteriolar Essential Hypertension in Active Tuberculosis; Their Rare Association, *Am. J. M. Sc.* 188:712 [Nov.] 1934) found one instance in 240 cases. In eighty postmortem examinations on patients dying with hypertension, however, Ayman reported that there were as many having old foci of tuberculosis as in patients not having hypertension. The lower incidence of tuberculosis, therefore, cannot be due to lack of infection.

In large sanatoriums the records show less than 0.5 per cent essential hypertension in admitted patients clinically and about 0.4 per cent in those coming to autopsy.

Hypertension in general is quite prevalent, as indicated by Alvarez (Blood Pressures in Fifteen Thousand University Freshmen, *Arch. Int. Med.* 32:17 [July] 1923) in studies on university students. Forty-five per cent had systolic pressures over 130 and in 22 per cent they were over 140. It is not necessarily associated with older age groups but is prone to manifest itself early in life and be associated with sthenic types. As age advances, however, it tends to become exaggerated.

A follow-up study by the same author (Alvarez, W. C., and Stanley, L. L.: Blood Pressures in Six Thousand Prisoners and Four Hundred Prison Guards, *Arch. Int. Med.* 46:17 [July] 1930) on prisoners and prison guards revealed that prisoners had pressures in general from 10 to 15 points lower than the

guards, perhaps because of the difference in diet and strain. There was in general, however, the same tendency, but the percentage of abnormal pressures was less than half that found in students. Particularly was this true of the prisoners. According to Adson and his associates (Adson, A. W., and Allen, E. V.: Essential Hypertension: I. General Considerations, *Proc. Staff Meet., Mayo Clin.* 12:1 [Jan. 6] 1937), 15 per cent of all adults and 23 per cent of persons all over 50 who die have hypertension. Brown (Essential Hypertension, *M. Clin. North America* 19:517 [Sept.] 1935) states that about 98 per cent of hypertension is of the "essential" type and that it is prone to be familial. Somewhere in the immediate ancestors a person will be found having the tendency. It is truly a "high pressure" disease of the West, for orientals rarely have it. Another sidelight on the type of hypertension is afforded by Arthur Fishberg (Anatomic Findings in Essential Hypertension, *Arch. Int. Med.* 35:650 [May] 1925), who states that he found 88 per cent of his cases of hypertension to be the "essential" variety on postmortem examination. The total number of cases of essential hypertension represents, therefore, well over 7 per cent, contrasted with hypertension in tuberculous patients, which occurs in well under 1 per cent. The disparity cannot all be attributed to the difference in age incidence of the two diseases.

The facts are that tuberculosis itself tends to lower the blood pressure and tends to develop more in the asthenic types, while hypertension has a tendency to appear more in the sthenic or athletic types. The assumption is that there is either something to cause tuberculosis to develop in the hypotensive patient or something to cause the hypertensive person to resist it, but the relationship of the state of nourishment, heredity and constitution, with the divergent courses of the respective diseases, is an unsolved problem and one that fills many pages of medical literature.

POSSIBLE ACNE NECROTICA MILIARIS OF SCALP

To the Editor:—My daughter, aged 10, healthy, blonde, with a luxuriant growth of hair, within the past week or ten days has displayed minute petechial spots on her scalp. These are first noticeable over the occiput but now are present also on the vertex. There is no itching but the scalp feels tender while the hair is being combed. Verrin are totally absent. My wife is worrying because two acquaintances living at distant points relate the same syndrome, which resulted in almost complete loss of hair. There is no dermatologist within 300 miles of here. I am almost totally bald but would gladly sacrifice the remaining isolated hairs that I possess to keep my daughter from becoming bald.

M.D., South Dakota.

ANSWER:—It is inferred from the wording of the query that no petechiae were found on other parts of the skin. A petechial eruption confined to the scalp is a rare phenomenon. If the doctor's observation is correct, the child should be thoroughly examined clinically and by all appropriate laboratory procedures to determine the cause of her purpura. Naegeli warns that general disease must always be suspected even though the petechial eruption is very limited in extent. Scurvy, the essential purpuras, thrombopenic, arthritic or abdominal, the blood dyscrasias, tonic, allergic and infectious causes must all be considered.

Is it possible that the doctor has mistaken small blood crusts on the scalp for petechiae? True purpuric lesions are usually smooth macules of from bright to dark red, from which it is impossible to express the blood and to blanch them by pressure with a glass lens or slide. Blood crusts occur frequently on the scalp, usually mixed with crusts that are not hemorrhagic. A disease characterized by tiny crusts of this nature was described by Sabouraud in 1928 and later in this country by J. E. Lane (Acne Necrotica Miliaris of the Scalp, *Arch. Dermat. & Syph.* 28:10 [July] 1933) and by Hamilton Montgomery (Acne Necrotica Miliaris of the Scalp, *ibid.* 36:40 [July] 1937). The lesions are from 1 to 3 mm. in diameter, occurring in crops of a dozen or less, more often on the occiput, but they may occur on any part of the scalp. They are often accompanied by itching and sometimes by dandruff or even outspoken seborrheic dermatitis, but the loss of hair is seldom seen and then is probably due to the seborrheic condition. The crusts are preceded by minute vesicles and are said to leave tiny scars; but these are very superficial and do not cause alopecia. Sabouraud considered the stapylomycosis the cause of the disease and this theory is borne out by the prompt effect of mercurial preparations. Ammoniated mercury ointment is the sovereign remedy; but though it causes prompt disappearance of the lesions it does not cure the disease, which recurs at varying intervals. Between attacks an alcoholic mercurial lotion may be used, such as mercury bichloride 0.2 Gm., spirit of formic acid 15 cc. and sufficient compound spirit of myrcia to make 90 cc. This can be applied with a medicine dropper once a day and rubbed into the scalp thoroughly with the fingers. During the use of mercurials it is well, on

theoretical grounds at least, to examine the child's urine once a week or once in two weeks. A possible sensitization to mercury may be guarded against by applying a patch test of 3 per cent white precipitate ointment to the back for forty-eight hours before use of the ointment therapeutically. The wisdom of this has recently been emphasized by J. H. Mitchell. If no irritation results from the patch test (do not confuse the irritation from adhesive plaster) in two days, it may be assumed that the skin is not sensitized to mercury.

If, in addition to the treatment of the vesicular eruption the patient is taught to brush her hair vigorously once a day, her parents need not worry about the loss of her hair within many years, barring, of course, other disease.

GLYCERIN, AURALGAN AND OTITIS MEDIA

To the Editor:—Is there any corroboration of the claims made for the type of glycerin used in auralgan as given in the accompanying folder, which you may have seen? In our section many of the younger pediatricians are resorting to drops instead of incision in acute otitis media in infants in which there is otologically a definite indication for paracentesis. Discussion on the subject two years ago with Dr. Lyman Richards of Boston elicited the same information from him concerning the practice of some pediatricians in his section.

M.D., New York.

ANSWER.—The Council on Pharmacy and Chemistry has made no examination of Auralgan, manufactured by the Doho Chemical Corporation, nor has any firm requested the Council to consider the preparation. According to advertising distributed in 1935, "Auralgan is an absolutely anhydrous solution of 5% Pyrazolon phenyldimethyl and other valuable anesthetics, not subject to the International Opium Convention, in pure glycerol of the highest specific gravity, manufactured by the Doho process exclusively." It will be noted that the promoter uses the little known chemical term "pyrazolon phenyldimethyl" instead of the more common name "antipyrine." It also fails to disclose the identity of the "other valuable anesthetics." Auralgan is marketed as a "conservative treatment in otitis media and aural pains." The preparation is claimed to possess certain physical properties not possessed by other solutions used in the treatment of diseases of the ear. The promoter, however, neglects to cite the evidence on which the special claims advanced in the advertising are based, and, until such evidence is furnished, a proper degree of skepticism would seem to be quite desirable. From the foregoing it appears that Auralgan is a preparation of semisecret composition marketed with extravagant and unsubstantiated claims.

There is no good basis for claiming that antipyrine is an efficient local anesthetic on skin surfaces. Furthermore, even if it were true that the glycerin in this preparation is of a higher quality and is more anhydrous than U. S. P. glycerin, this difference is probably of only theoretical value. Both of these glycerins will take up water quickly, and it is sufficient only to open the bottle or put the medication in the ear to have this take place. The more anhydrous the glycerin, the more apt would it be to do so.

POSSIBLE ADRENAL DEFICIENCY

To the Editor:—A man aged 50 complains of insomnia and constipation that cannot be corrected with ordinary medication and diet. He is a good swimmer but at times gets attacks of weakness so that he cannot swim the full length of the pool. His temperature is subnormal, about 96 F., until noon. Thereafter it is normal until midnight. The electrocardiogram, urinalysis, metabolic tests and blood counts are normal. He has a constantly subnormal blood pressure, about 105 systolic, 75 diastolic. A diagnosis of adrenal gland deficiency has been made and whenever the patient takes adrenal cortex pills for several weeks the symptoms clear up. If this is the correct diagnosis, what are the prospects of having to discontinue the cortex pills in the future? The patient weighs 188 pounds (85 Kg.).

M.D., California.

ANSWER.—The answer to this question depends on the accuracy of the diagnosis of adrenal deficiency. In the absence of more definite symptoms, it is one of the most difficult diagnoses to establish. The patient's blood pressure level is not necessarily subnormal for him. One would like to know whether he ever had a higher blood pressure when he was in good health. It might be possible to prove the presence of adrenal insufficiency by carrying out the serum and urine electrolyte study described by H. H. Cutler, M. H. Power and R. M. Wilder (*THE JOURNAL*, July 9, 1938, p. 117). However, it is not known how early in adrenal cortical deficiency this test becomes useful. The lungs and adrenal regions should be roentgenographed to rule out tuberculosis and calcification, respectively.

If the patient has mild adrenal deficiency, treatment with high salt intake, about 15 Gm. daily in addition to the ordinary

seasoning, should control the symptoms. Adrenal cortex extract is usually necessary in the more severe cases or during exacerbation of symptoms as the result of respiratory infections, exposure to extreme heat or cold, surgical procedures and shock. The type of extract to use is a serious problem because of the uncertain potency of many commercial extracts. The glycerin extract prepared for oral administration has been shown to be effective in typical but low grade Addison's disease when given in two to four times the amount necessary by the parenteral route. A dosage corresponding to at least 5 Gm. of fresh adrenal cortex daily should be prescribed. If the pills contain 2 grains (0.13 Gm.) of cortex each, forty pills a day would be required as a minimum. During emergencies, parenteral administration of a potent extract is the only safe procedure for rapid effects. Whether the patient can get along without adrenal cortex extract will depend on his response to salt treatment alone, on the rate of progression of the underlying adrenal disease and on the occurrence of crises. If the diagnosis remains in doubt, substitution of placebo pills should be tried during a period when the patient is on a low salt intake and under close observation.

FUNCTIONAL NEUROSIS

To the Editor:—A man aged 43, to all appearances in perfect health, complains of a numbness or dead feeling, as he expresses it, on the left side of the head, including the left side of the mouth, left arm and forearm but not including the shoulder, elbow or wrist joints, the left thigh but not the hip joint, the left leg and the knee joint as well as the ankle joint and the foot. When he puts his leg down he is not sure of its ability to support him and he has had several falls. At first he had pains in the side of his head and neck which felt as if they were "deep in the head," as he expresses it. He has not experienced these pains in the past two years. The trouble is of three years' duration and he has it only in February, March and sometimes April. If he can get out on a warm day and play golf, the numbness clears up. He leads a sedentary life in a hardware store and seldom takes a vacation. Physical examination showed nothing abnormal: blood pressure 130 systolic, 70 diastolic; reflexes normal; urinalysis normal. No foci of infection could be located. The blood showed 5,300,000 red cells, 6,000 white cells and 95 per cent hemoglobin, and the Wassermann reaction was negative at three different times. The family history is negative except that two cousins on his father's side have a psychosis. The patient himself shows some mental instability and will break down and cry for a trivial reason or for none at all. He is a good business man and has plenty of intelligence. Some years ago he had ulcers of the stomach but received treatment at John Hopkins Hospital and elsewhere and has recovered completely, so far as every examination in the past two years could determine. He has been to hospitals for his present trouble but has received no help. He was told that he was neurotic and the physicians he saw let it go at that. He does not seem neurotic to me or he would complain more frequently than he does. Any advice that you can give me about the cause and treatment or suggestions concerning further examination would be deeply appreciated.

M.D., Virginia.

ANSWER.—From the information given, it is suspected that this is a case of a functional neurosis. However, it would be safe to have an examination by a neurologist if no such examination has been made within the past year. If organic disease can be excluded, it will be necessary to go into the patient's mental life and find out what problems and conflicts may have played a part. If it is possible to unravel the past and explain to him how he got to be the way he is, a cure might be obtained.

"EYE SHADOWS"

To the Editor:—A man aged 28 gives a history of having had eye shadows since childhood. The shadows are noticeable, being quite dark particularly in the region of the inner canthus and sweeping down across the lower lid on each side. There is no puffiness and the skin, except for its color, is perfectly normal. The patient is well developed, well nourished and highly intelligent, smokes and drinks a little, does not dissipate and is the father of a healthy year old child. The family history is essentially negative, the father, mother and six brothers and sisters all living and well. Several brothers and sisters have the same tendency to eye shadow but not nearly so marked as has the patient in question. His complexion is good. I can find nothing in a complete physical examination which is abnormal or which might explain the trouble. The defect is only cosmetic but nevertheless real. He informs me that regular hours and long periods of rest improve the shadows so little as to be negligible. The eyes are normal. What, if anything, can be done about a condition like this?

M.D., Minnesota.

ANSWER.—In all probability the "eye shadows" are merely the darkened areas of skin due to a superficial location of the veins at the margin of the orbit. This is an anatomic condition and not a pathologic one. When the patient is tired, the veins are apt to be somewhat fuller than they are otherwise and the shadows are somewhat darker. There is no satisfactory treatment.

EOSINOPHILIA

To the Editor:—A woman aged 46, 5 feet 6 inches (168 cm.) tall, weighing 198 pounds (89.8 Kg.), complains of cramplike abdominal pains of six weeks' duration. These trouble her usually in the evenings after dinner or soon after retiring at night. They are sharp and stablike, localized in the epigastrium beneath the left costal margin or in the lower part of the abdomen. In addition, she feels that the abdomen is distended and heavy. She notices dyspnea on rather mild exertion but she has gained a great deal of weight lately, 40 pounds (18 Kg.) in the last year. There has been some abnormal looseness of the bowels but no actual diarrhea. Previous to the onset of the symptoms mentioned, the patient had been in good health except for mild menopausal symptoms. The menopause occurred nine months ago. The past history was essentially negative. The patient has lived in San Francisco since birth. She had only the ordinary diseases of childhood. She had three normal pregnancies and deliveries. On examination she was not acutely ill. The excess weight is localized largely over the abdomen. The blood pressure was 140 systolic, 90 diastolic, the chest was clear, the heart was of normal size and the rhythm was regular. The abdomen was obese but soft, with little palpable gas. The liver, kidneys and spleen were not palpable. Pelvic examination revealed a marked prolapse of the uterus with rather severe cystocele and rectocele. The blood count revealed red cells 5 million, hemoglobin 95 per cent, white cells 25,000, neutrophils 17.3 per cent, nonfilaments 0.7 per cent, lymphocytes 12.3 per cent, monocytes 1.7 per cent, eosinophils 68 per cent. The examinations of the urine and of the stool were negative. Because of the marked eosinophilia with gastrointestinal symptoms, an attempt was made to detect a possible parasite. Repeated examinations of the stool in the past month have all been negative. Cutaneous tests for trichina were negative. X-ray examination of the abdomen revealed a slight enlargement of the spleen but not beneath the costal margin. The patient was given a bland 1,000 calory diet. Half grain (0.032 Gm.) doses of phenobarbital relieved the pains to some extent. In general she has been feeling somewhat better. On one occasion she endeavored to cure herself with a large dose of castor oil and was quite ill for a day with severe abdominal cramps, nausea and vomiting. The blood count has been repeated weekly and remains much the same as the first one. The great majority of the eosinophils are adults with two and three lobed nuclei. There are about 2 per cent of eosinophil metamyelocytes. Diligent search reveals an occasional eosinophil myelocyte. The eosinophils are quite typical and there is no question of confusion with neutrophils. Will you give me your opinion of this case and suggest what further procedures may be advisable to determine the diagnosis.

M.D., California.

ANSWER.—This question involves a differential diagnosis between the numerous causes of eosinophilia. Osgood lists forty-six such causes. These may be found in any good textbook on hematology and many of them are possibilities in this case.

It seems probable that the cause of such an eosinophilia as is described here will be found in trichinosis, arsenic poisoning, eosinophilic leukemia, periarteritis nodosa, Hodgkin's disease or lymphosarcoma. Of these, the first three are the most likely.

Trichinosis is suggested by the abdominal pain and the looseness of the bowel that appeared coincidentally with the eosinophilia. The eosinophilia in trichinosis is greatest when the parasites are burrowing through the intestinal wall. The negative reactions of the stool and skin do not positively preclude the diagnosis. Infestation frequently occurs without pain or soreness of the muscles.

Eosinophilic leukemia is rare but is a possibility. The presence of metamyelocytes and myelocytes and the slight splenomegaly lend weight to this possibility. Examination of the sternal marrow would be helpful in investigating this possibility. The total leukocyte count may be expected to increase in leukemia.

Arsenic poisoning should be ruled out by a careful investigation.

While trichinosis still remains the best possibility, it seems doubtful whether biopsy of muscle or examination of the spinal fluid is justified as a diagnostic procedure. After six weeks of illness with improvement the patient is destined to recover from trichinosis and it would seem more logical to rule out the other possibilities.

DIGITALIS AND SYPHILITIC HEART DISEASE

To the Editor:—What is the rationale for the use of digitalis in syphilitic heart disease? My patient has a pulse varying between 96 and 124. The rhythm is good but the quality is poor.

Virgil F. Neumann, M.D., Norwich, Conn.

ANSWER.—In addition to slowing the heart rate, digitalis probably exerts a direct action on the myocardium, improving the strength of contractions and thus perhaps eventually leading to that great desideratum in congestive failure diuresis. When failure is associated with auricular fibrillation the benefit from digitalis has always been considered greater than when the rhythm is normal, so much so that at times, and in certain quarters, it has been the fashion to reserve digitalis almost exclusively for patients with auricular fibrillation. The whole matter has recently been illuminated in a careful clinical study reported by Gavey and Parkinson (Gavey, C. J., and Parkinson, John: *Brit. Heart J.* 1:27, 1939). They attempted to

evaluate the benefit derived from digitalis in heart failure with normal rhythm in cases taken from various etiologic groups. This series was then compared with a group of patients with auricular fibrillation, also from various causes. Taking each group as a whole, they found, as others have, that those with fibrillation benefited more from digitalis than those with normal rhythm. However, if cases of fibrillation due to rheumatic heart disease were omitted from the fibrillation group, the remainder showed no more benefit than the group with normal rhythm; that is, a patient with auricular fibrillation from hypertension or thyrotoxicosis responded no better to digitalis than similar cases of congestive failure in the group presenting normal rhythm. The authors concluded: "The real difference in the response of heart failure to digitalis lies not between auricular fibrillation and normal rhythm but rather between rheumatic auricular fibrillation and all other kinds of heart failure irrespective of rhythm."

It is, of course, rare to have auricular fibrillation associated with syphilitic heart disease, and in this respect the patient described in the query conforms to the rule. At the present time the great bulk of opinion favors the use of digitalis in chronic myocardial insufficiency, whatever the underlying disease and whether or not the rhythm is regular. It is assumed that appropriate antisyphilitic treatment is also part of the program in this particular instance.

ROUTINE ADMINISTRATION OF TETANUS TOXOID

To the Editor:—I have been advised to use tetanus toxoid in a routine way in children or the combined diphtheria and tetanus toxoid. Does this meet with approval or is it still experimental?

Don S. Fraser, M.D., Panama City, Fla.

ANSWER.—The advice concerning the use of tetanus toxoid is believed good. About 1936 the administration of tetanus toxoid was made compulsory for all soldiers as well as for all animals in the army of France.

Ramon urges the routine administration of tetanus toxoid and diphtheria toxoid combined for all children. This method has been adopted in a number of places in France. The plan has progressed beyond the experimental stage.

EXTRAORDINARY ACAROPHOBIA

To the Editor:—A patient has an infection of the skin and hairy regions which has dragged along for the past year without the desired results from the treatment administered. The symptoms are as follows: There is a generalized migrating sensation much more pronounced over the scalp and other hairy regions. Expulsion of minute black specks occurs more or less continuously for a period of six hours every thirty-six hours. Occasionally (not with every expulsion) there is expelled adult parasitic life that has been identified as (a) *Drosophila* (fruit fly), (b) *Catoroma* (small beetle), (c) *Anthididae* (small beetle), (d) *Latridiidae* (small), (e) dermestid larva *Attagenus* (small beetle), (f) isopod "sand flea" (small crustacean), (g) fly genus? ant genus? nits? This identification was made from material gathered from expulsions of the scalp over a period of several months. The hair on the surface becomes intensely blacker during the migratory phenomenon but quickly assumes its normal color. If it is extricated with a pair of thumb forceps the hair appears thicker and blacker and the bulb quite large and black. A stinging feeling is produced when the hair is making its way to the surface of the skin and tends to perforate. There are no other symptoms of any definite value, and no constitutional disturbance is produced. One condition that is of great annoyance to the patient is the migrating sensation from the scalp down over the forehead to the brow and eyelids. The hair is short (one-eighth inch in length) and appears to migrate just below the epidermis, making its way to the edge of the lids. In order to afford relief, it is extricated as soon as it makes its appearance. I shall be grateful if you could devise a good treatment for this condition and, if possible, tell me whether any serum or vaccine could be made to combat infection more specifically.

M.D., New Jersey.

ANSWER.—It is quite obvious that the diverse organisms from this patient's skin did not arrive there naturally. The conclusion is forced that the entire affair is feigned and fraudulent. In the usual case of phobia for parasites the patient sincerely believes himself to be infested with insects. He has a delusion. The diagnosis in such a case is acarophobia. The subject digs, scrapes or cuts away small bits of skin, which he presumes to be parasites. He will bring numbers of such specimens to the physician as evidence of infestation. There may have been actual itching present before the fancied infestation occurred. It is most difficult to convince these patients that there is no actual infestation. The aid of a psychiatrist is sometimes needed. In such a case as the present one the procedure is even more difficult. It is necessary to use the greatest tact and at the same time a firm approach. An attempt should be made to discover the patient's motive in feigning this peculiar process. The service of a specialist in nervous and mental diseases might be of benefit in solving this peculiar complex.

TREATMENT OF SYPHILIS AFTER
ARSENICAL DERMATITIS

To the Editor:—A man aged 58 has been under treatment for early syphilis, a chancre being present when treatment was begun. He was given a course of ten treatments with neocarsphenamine at weekly intervals. At the end of this period of treatment an arsenical dermatitis appeared. This was treated with sodium thiosulfate and the dermatitis disappeared. He is now being given a course of bismuth injections. I should like to know whether it is wise to resort again to the arsenicals for treatment and if so whether or not any of the other arsenicals are considered less toxic and safer to use than neocarsphenamine.

M.D., California.

ANSWER:—A 58 year old patient who has demonstrated an intolerance for arsphenamine as evidenced by an arsenical dermatitis should not be subjected to further treatment of this type until at least from six to eight months has elapsed. In the meantime the bismuth therapy must be continued. If at the end of six months there is evidence that the bismuth has failed to control the disease, the use of small doses of mapharsen might be employed, with however extreme caution, at least a week or ten days between injections and close scrutiny for evidence of recurrence of the dermatitis. On the other hand, if the clinical course has been satisfactory and the serologic tests have become weakly positive or negative, it would be advisable to continue only with the bismuth and not attempt further arsenical therapy.

Many patients have been rid of their syphilis with less than ten injections of arsphenamine, and this patient, especially in view of his age, should be treated cautiously with bismuth compounds until a sufficient time has elapsed to determine the effect of this type of treatment rather than run the risk of producing a second arsenical dermatitis.

OKRA AND ARTICHOKE

To the Editor:—Please let me know something about okra and artichokes other than with regard to their protein and carbohydrate content. Do they have any ferment content or have they any peculiar value in stomach disorders? Are they contraindicated in a mild peptic ulcer syndrome? I have a patient who pulled a stomach tube out before a gastric analysis was completed and refuses to permit another attempt. The readings obtained were:

	Free Hydrochloric Acid	Total Acidity
Fasting	0	11
15 minutes	4	18
25 minutes	22	40

Stale bread and water constituted the test meal. Units are expressed as cubic centimeters of tenth normal sodium hydroxide. Would this be sufficient to be called hyperacidity, compatible with peptic ulcer? Are occasional one day attacks of mild diarrhea part of a peptic ulcer syndrome?

M.D., New York.

ANSWER:—Okra was of interest for a while because a vegetable mucin was being obtained from it. Artichokes are of interest mainly because of the peculiar types of sugar which they contain. There seems to be no knowledge of any particular ferment content. If there should be any, it would be destroyed in cooking. There should be no contraindications to the use of these foods in mild cases of ulcer except perhaps that artichokes contain a great deal of fiber.

The patient's acidity is well within the limits of normal. Any reading is compatible with the presence of a peptic ulcer. Diarrhea is not a symptom of peptic ulcer.

VITAMINS AND PYORRHEA

To the Editor:—Has vitamin C any effect in preventing, checking or curing pyorrhea of the gums? Are any of the vitamins particularly valuable in pyorrhea?

Matthew Karasek, M.D., Shidler, Okla.

ANSWER:—The most certain thing that is known about pyorrhea is that different cases demonstrate widely different pathologic processes. There is undoubtedly a type of pyorrhea related to scurvy if not caused by it. In this type vitamin C is necessary both in prevention and in cure. The relation of other vitamins, especially vitamin A, to supporting tissues of the teeth is not so clear but some relation has been reported by various investigators. There is also evidence that in some cases the condition is related to endocrine disturbances.

According to Boyle, Bessey and Wolbach (*Proc. Soc. Exper. Biol. & Med.* 36:733 [June] 1937) "The essential characteristic of the diffuse alveolar atrophy type of pyorrhea, which is inability of periodontal tissues to withstand functional stress, has been reproduced in guinea pigs maintained on diets deficient in ascorbic acid. The histological details in bone and connective tissues of these scorbutic animals are identical with those found in human periodontal disease of this type."

There is a considerable amount in the literature with reference to experimental programs regarding vitamin deficiencies, some

of which involve the pathology of the gingivae and supporting tissues and there is some evidence that vitamin D, calcium and phosphorus are involved in the maintenance of normal teeth and gums. The usefulness of any of these or of vitamin C in the treatment of pyorrhea is not, however, clearly established.

SYSTOLIC MURMUR AND HORN PLAYING

To the Editor:—A youth aged 12, normal except for a systolic apical murmur brought on by exercise, wishes to learn to play a French horn. Are there any contraindications for him to do so?

Louis L. Fiorito, M.D., Chicago.

ANSWER:—If the boy has a definite lesion with a certain degree of myocardial insufficiency, his vital capacity might be sufficiently reduced to make horn playing difficult or impossible. But the mere presence of a murmur, as in the case described, does not in itself imply disease of the heart. There is a well known connection between players of wind instruments and pulmonary emphysema in later life. Horn playing might therefore conceivably be said to affect the heart, although remotely. Any attempt to relate the case under consideration to such speculations must be dismissed as mere theorizing. There would seem to be no medical reason why the young man should not take up the French horn.

TRANSPLANTATION OF THE EYE AND CORNEA

To the Editor:—Has any progress been made in recent years in the transplantation of human eyes?

M.D., California.

ANSWER:—The transplantation of the entire eyeball is a fanciful dream which unfortunately can never come true. While it is perfectly possible in experimental animals to transplant the eyeball and have it live, there is no possibility of producing vision in such a transplant. The optic nerve is a part of the brain and as such does not regenerate when once dead. But transplantation of the cornea of the human eye is an accomplished fact, with adequate clinical evidence in support. However, this is applicable only in such cases in which vision is interfered with by scars of the cornea. Destruction of the remainder of the visual apparatus vitiates the value of such transplants. The man in the United States who has had great experience in corneal transplantation is Dr. Ramon Castroviejo of Columbia University of New York, who now has well over 200 such operations to his credit.

GASTROINTESTINAL THRUSH

To the Editor:—A patient aged 3½ months has suffered from thrush since birth. In addition to local symptoms there is refusal to eat, gas, constipation and difficulty in swallowing. None of these symptoms are controlled by the usual formula regulations. Stool culture shows *Monilia albicans*. X-ray films of the stomach show a six hour retention. Treatment has consisted of local application of 1 per cent gentian violet and exposure to a sunlamp. Could gentian violet or any other medication be given by mouth on the basis that there are localized lesions in the gastrointestinal tract as well as in the mouth? Any help that you can give me will be appreciated.

M.D., New York.

ANSWER:—Generalized thrush is highly resistant to treatment. If it is confined to the gastrointestinal tract, recovery will ensue, although the response to any form of treatment will be slow.

Gentian violet is one of the best remedies for gastrointestinal thrush and can be used both locally and orally. Skimmed acid milks or buttermilk mixtures are best used for the feeding with a minimum of carbohydrate added. Honey or a preparation of maltose and dextrin is the carbohydrate of choice. Cottage cheese can be given at 3½ months and is well tolerated. Heliotherapy or the sun lamp and much open air exposure and the use of cod liver oil or cod liver oil concentrates are valuable aids in the general treatment, as is also the use of additional vitamins C and B and a moderate amount of nicotinic acid.

VIRUS DISEASES NOT CONTAGIOUS DURING
INCUBATION PERIOD

To the Editor:—Are those common infectious diseases of childhood generally thought to be caused by a virus contagious during incubation period? Does the answer also apply to whooping cough?

M.D., District of Columbia.

ANSWER:—It is generally believed that an infectious disease due to a virus is not contagious during the incubation period. Rabies and smallpox are examples that would uphold this view. Whooping cough is not a virus disease and is not regarded as being contagious during the period of incubation.

Medical Examinations and Licensure

COMING EXAMINATIONS

STATE AND TERRITORIAL BOARDS

Examinations of state and territorial boards were published in THE JOURNAL, June 24, page 2627.

NATIONAL BOARD OF MEDICAL EXAMINERS

NATIONAL BOARD OF MEDICAL EXAMINERS: Parts I and II. Medical centers having five or more candidates desiring to take the examination, Sept. 11-13. Ex. Sec., Mr. Everett S. Elwood, 225 S. 15th Street, Philadelphia.

SPECIAL BOARDS

AMERICAN BOARD OF ANESTHESIOLOGY: An Affiliate of the American Board of Surgery. *Written*. Various places throughout the United States, Sept. 9. Applications must be filed by July 11. *Oral*. Part II. Philadelphia, Oct. 14-15. Sec., Dr. Paul M. Wood, 745 Fifth Ave., New York.

AMERICAN BOARD OF DERMATOLOGY AND SYPHILOLOGY: *Written*. Various large cities in the country, Oct. 9. Applications must be received by the Secretary by Sept. 1. *Oral*. Philadelphia, Nov. 3-4. Sec., Dr. C. Guy Lane, 416 Marlboro St., Boston.

AMERICAN BOARD OF INTERNAL MEDICINE: *Written*. Various sections of the United States, Oct. 16 and Feb. 19. Formal application must be received before Aug. 20 for the Oct. examination and on or before Jan. 1 for the Feb. examination. Sec., Dr. William S. Middleton, 1301 University Ave., Madison, Wis.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY: *Written examination and review of case histories (Part I) for Group B candidates will be held in various cities of the United States and Canada, Dec. 2. Applications for admission to Group B, Part I, examinations must be on file not later than Oct. 4. General oral and pathological examinations (Part II) for all candidates (Groups A and B) will be conducted in Atlantic City, N. J., June 6-8. Applications for admission to Group A, Part II examinations must be on file not later than March 15. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh (6).*

AMERICAN BOARD OF OPHTHALMOLOGY: *Written*. August 5 and April 6. Formal application must be received before July 1 for the August examination and before January 1 for the April examination. *Oral*. Chicago, Oct. 7 and New York, June 10. Sec., Dr. John Green, 6830 Waterman Ave., St. Louis.

AMERICAN BOARD OF ORTHOPAEDIC SURGERY: Boston, January. Applications must be filed on or before Nov. 1. Sec., Dr. Fremont A. Chandler, 6 N. Michigan Ave., Chicago.

AMERICAN BOARD OF OTOLARYNGOLOGY: Chicago, Oct. 6-7. Sec., Dr. W. P. Wherry, 1500 Medical Arts Bldg., Omaha.

AMERICAN BOARD OF PATHOLOGY: Memphis, Nov. 22-23. Sec., Dr. F. W. Hartman, Henry Ford Hospital, Detroit.

AMERICAN BOARD OF PSYCHIATRY AND NEUROLOGY: New York, December. Sec., Dr. Walter Freeman, 1028 Connecticut Ave. N.W., Washington, D. C.

AMERICAN BOARD OF RADIOLOGY: Atlanta, Ga., Dec. 9-11. Sec., Dr. Byrl R. Kirklin, 102-110 Second Avenue S.W., Rochester, Minnesota.

AMERICAN BOARD OF SURGERY: *Part I (Written)*. Simultaneously in various centers throughout the United States, Oct. 9. Applications must be received by the Secretary not later than Aug. 15. Sec., Dr. J. Stewart Rodman, 225 S. 15th St., Philadelphia.

Rhode Island April Examination

Dr. Robert M. Lord, secretary, Rhode Island State Board of Examiners in Medicine, reports the oral, written and practical examination held at Providence, April 6-7, 1939. The examination covered twenty subjects and included fifty questions. An average of 80 per cent was required to pass. One candidate was examined and passed. The following school was represented:

School	PASSED	Year Grad.	Per Cent
Georgetown University School of Medicine.....	(1937)		87

Tennessee March Examination

Dr. H. W. Qualls, secretary, Tennessee State Board of Medical Examiners, reports the written examination held at Memphis, March 22-23, 1939. The examination covered ten subjects and included 100 questions. An average of 75 per cent was required to pass. Twenty-five candidates were examined, all of whom passed. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
College of Medical Evangelists.....	(1938)		85.9
Univ. of Pennsylvania School of Medicine.....	(1936)		87.9
University of Tennessee College of Medicine.....	(1938)		85.6
(1939) 81.6, 83.5, 84, 84.8, 85, 85.5, 86.2, 86.3, 86.5, 86.6, 86.6, 86.8, 87.3, 87.4, 87.6, 88.3, 88.6, 88.8, 88.9, 91.2			
University of Toronto Faculty of Medicine.....	(1934)		90.4

Three physicians were licensed by endorsement from January 6 through January 31. The following schools were represented:

School	LICENSED BY ENDORSEMENT	Year Grad.	Per Cent
University of Louisville School of Medicine.....	(1936)		Kentucky
Johns Hopkins University School of Medicine.....	(1933)		N. B. M. Ex.
University of Toronto Faculty of Medicine.....	(1921)		Ohio

Arizona April Report

Dr. J. H. Patterson, secretary, Arizona State Board of Medical Examiners, reports the written examination held at Phoenix, April 11-12, 1939. The examination covered ten subjects and included 100 questions. An average of 75 per cent was required to pass. Five candidates were examined, four of whom passed and one failed. One physician was licensed by reciprocity. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
College of Medical Evangelists.....	(1938)		77.3
Chicago Medical School.....	(1938)		81.4
Creighton University School of ..			77.1
University of Wisconsin Medical ..			77.4

School	FAILED	Year Grad.	Per Cent
Chicago Medical School.....	(1938)		69.2*

School	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
Marquette University School of Medicine.....	(1929)		Wisconsin

* This applicant has received the M.B. degree and will receive the M.D. degree on completion of internship.

Colorado April Report

Dr. Harvey W. Snyder, secretary, Colorado State Board of Medical Examiners, reports the written examination held at Denver, April 5-7, 1939. The examination covered eight subjects and included 159 questions. An average of 75 per cent was required to pass. Six candidates were examined, all of whom passed. Two physicians were licensed by endorsement. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
School of Medicine of the Division of Biological Sciences.....	(1937)		80
Osteopaths ..		76, 79, 80, 80, 82	

School	LICENSED BY ENDORSEMENT	Year Grad.	Per Cent
Johns Hopkins University School of Medicine.....	(1936)		Maryland
Harvard Medical School.....	(1935)		N. B. M. Ex.

* Licensed to practice medicine and surgery.

Hawaii April Examination

Dr. James A. Morgan, secretary, Board of Medical Examiners, Territory of Hawaii, reports the oral and written examination held at Honolulu, April 10-13, 1939. The examination covered ten subjects and included eighty questions. An average of 75 per cent was required to pass. Eight candidates were examined, all of whom passed. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
Georgetown University School of Medicine.....	(1938)		80.5
Emory University School of Medicine.....	(1937)		85.3
University of Louisville School of Medicine.....	(1932)		81.4
Tulane University of Louisiana School of Medicine.....	(1927)		76.1
Johns Hopkins University School of Medicine.....	(1935)		79.4
Detroit College of Medicine and Surgery.....	(1932)		77.7
University of Nebraska College of Medicine.....	(1935)		82.2
Medical College of Virginia.....	(1933)		87.2

Two physicians were licensed by endorsement on March 9 and March 31. The following schools were represented:

School	LICENSED BY ENDORSEMENT	Year Grad.	Per Cent
Stanford University School of Medicine.....	(1929)		N. B. M. Ex.
Jefferson Medical College of Philadelphia.....	(1937)		N. B. M. Ex.

Nevada May Examination

Dr. John E. Worden, secretary, Nevada State Board of Medical Examiners, reports the written examination held at Carson City, May 1-3, 1939. The examination covered twelve subjects and included ninety-six questions. An average of 75 per cent was required to pass. Two candidates were examined, both of whom passed. One physician was licensed by endorsement after an oral examination. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
University of Southern California School of Medicine.....	(1939)		87.7
Loyola University School of Medicine.....	(1937)		78

School	LICENSED BY ENDORSEMENT	Year Grad.	Per Cent
Washington University School of Medicine.....	(1924)		N. B. M. Ex.

Book Notices

Nutrition: The Newer Diagnostic Methods. Proceedings of the Round Table on Nutrition and Public Health. Sixteenth Annual Conference of the Milbank Memorial Fund March 29-31, 1938. Paper. Price, \$1. Pp. 192, with illustrations. New York, 1938.

Physicians interested in the newer developments in methods of assessing the nutritional status of patients will find the present volume most useful, because it contains material described in no other single volume. The present little book contains the papers presented in the section on public health at the sixteenth annual conference of the Milbank Memorial Fund. A. Graeme Mitchell discusses the medical aspects of problems of nutrition. The late T. Wingate Todd summarizes his work on the use of roentgenology in assessing the nutritional state and in detecting certain deficiency diseases. There is an article on dark adaptation and the diagnosis of avitaminosis A by Selig Hecht, and there is another by Jacob B. Feldman on the use of the photometer in detecting latent avitaminosis A. Soma Weiss discusses the application of electrocardiography in the detection of avitaminosis B₁; S. Z. Levine and E. Marples report on color tests for vitamin B₁, and Tom Spies contributes a chapter on the relation of nicotinic acid to pellagra with particular reference to therapeutic studies and a diagnostic test. Chester J. Farmer and Arthur F. Abt have a chapter on the titration of plasma ascorbic acid as a test for latent avitaminosis C. G. M. Guest has described his work on hematologic methods and newer procedures for the detection of nutritional anemia. John B. Youmans discusses the diagnosis of nutritional edema, with particular reference to the determination of plasma proteins and consideration of their behavior. A feature of the book is the inclusion of comments from the round table discussions following the presentation of each paper. It is a far cry from the older methods of evaluating the nutritional status by physiologic examination to the present methods described in this book. Possibilities for future investigations are truly enormous, and the procedures described in this book will be important in obtaining the necessary data.

Trauma and Internal Disease: A Basis for Medical and Legal Evaluation of the Etiology, Pathology, Clinical Processes Following Injury. By Frank W. Spicer, A.B., M.D., F.A.C.P. Cloth. Price, \$7. Pp. 593, with 43 illustrations. Philadelphia, Montreal & London: J. B. Lippincott Company, 1939.

This book seems to be merely a compilation of a multitude of reports which have appeared in connection with trauma and disease. The author acknowledges that he has depended almost entirely on the experience of others. Most of the material consists of case reports. Such highly controversial matters as trauma in relation to tuberculosis or heart disease are not convincingly presented. However, as the author shows, the fact that courts have allowed claims for damages because of supposed traumatic factors in pulmonary tuberculosis is important for physicians. The legal side is, however, inadequately presented. The bibliography is tremendous, but of the numerous reports about half are more than two decades old. Pathologic concepts have changed considerably during the postwar decades. The greatest fault is the failure to use the statistical approach to the subject. Too often there is "post hoc ergo propter hoc" reasoning. The book loses its appeal as a scientific text, which could be enhanced by citation of more legal decisions.

A Medical Survey of the Republic of Guatemala. By George Cheever Shattuck, Harvard School of Public Health, Boston, Mass. With the collaboration of Joseph C. Bequaert, Jack H. Sandground, Margaret M. Hiltferty and Samuel Drury Clark. Paper. Price, \$2.50. Pp. 253, with 8 illustrations. Washington, D. C.: Carnegie Institution of Washington, 1938.

The barrier of time and space between the United States and the tropics of South and Middle America disappears in proportion to the use of the airplane for passenger travel. It is quite possible for persons to leave the areas of infectious tropical diseases and enter the United States well within the incubation period of several dangerous diseases, such as yellow fever. Even transportation by ship affords some opportunities for the entry of the infectious diseases of middle and southern America, notwithstanding the highly efficient work of the United States Public Health Service at ports of entry. Thus the diseases of

the tropics constitute a threat to the health of the people of the United States. This well prepared publication is one of a long series produced under the auspices of the Carnegie Institution of Washington. It is based in part on first hand observations in Guatemala and in part on reports and statistical compilations prepared by various public health agencies in Guatemala. It contains, among many other items, an analysis of the vital statistics of Guatemala, a history of the infectious diseases of that country, chapters on malaria, leishmaniasis, syphilis, yaws, tropical anemia, goiter and myxedema, helminthic infestations and the insects of Guatemala. The population of Guatemala, of approximately 2,266,682, embracing both white persons and Indians, is distributed over areas geographically more different than any extremes in the United States. The Peten and coastal areas are distinctly tropical. The midwestern portion, or highlands, contain inhabited areas with an elevation in excess of 12,000 feet. The diseases of this country, while shared to some extent by the different areas, are in part peculiarly characteristic of the differences in terrain, altitude, temperature and vegetation. This book, while recognizing a high incidence of a great variety of infectious and noninfectious diseases, which constitute major national problems, pays merited tribute to the public health forces of this small republic. Designed as a highly technical, factual public health volume, it is so engaging in its description of public health problems and enterprises that it may be recommended alike to physicians and to the public.

Handbuch der Virusforschung. Herausgegeben von Prof. Dr. R. Doerr und Prof. Dr. C. Hallauer. Erste Hälfte: Die Entwicklung der Virusforschung und ihre Problematik. Morphologie der Virusarten. Die Züchtung der Virusarten ausserhalb ihrer Wirte. Biochemie und Biophysik des Virus. Bearbeitet von F. M. Burnet et al. Paper. Price, 66 marks. Pp. 547, with 71 illustrations. Vienna: Julius Springer, 1938.

This is a collective work by a most competent group of specialists in a field of remarkable activity, of astounding results and of greatest scientific significance. The viruses lie at the lowest margin of the living world or beyond it, depending on the concept of the limits of living substance. They appear to be protein substances capable of self propagation within living cells and to be composed of units mostly but not wholly beyond the limits of visibility or photographic detection even with the ultra-microscope. They can be centrifuged, filtered through graded collodion membranes, purified by filtration and high speed centrifugation from organic contaminants, and inactivated and reactivated by various chemical procedures. Their dimensions can be determined within limits and their activity retained between a series of crystallizations. They differ among themselves not only in their pathologic consequences but in dimensions and in physical and chemical properties. They can be cultivated in tissue cultures and grown on chick allantoic membranes.

The historical development of virus investigations and the emergence of their varied problems is presented by Dr. Doerr of the Hygienic Institute of Basel, the sizes of the species of viruses by Dr. W. J. Elford of the British National Institute of Medical Research of London, the use of the fluorescent microscope by Dr. Haitinger of Vienna and of staining methods by Dr. Kaiser of Vienna, the relation of inclusion bodies to viruses by Dr. G. M. Findlay of the Wellcome Bureau of Scientific Research in London, the laboratory investigation of kinds of viruses outside the host by Dr. Hallauer of the Hygienic-Bacteriologic Institute of Bern, the growth of viruses on the chorio-allantois of the chick embryo by Dr. E. M. Burnet of the Walter and Eliza Hall Institute in Pathology and Medicine in Melbourne, and the biochemistry and biophysics of viruses by Dr. W. M. Stanley of the Rockefeller Institute for Medical Research at Princeton. Each of these chapters ends with a full bibliography.

This galaxy of specialists has produced a work of the highest standard of scholarship, completeness and critical estimation of the results, which are often conflicting until some new technic has resolved the difficulty. The factors which add to the complexity of the problems are the differences among kinds of viruses, the effects of contaminating substances and the control which external factors exert over results.

Among the filter passers investigated, in the order of their dimensions, which range from 750 to 6 micromillimeters, are

Bacillus prodigiosus, *Spirillum parvum*, the virus of psittacosis, agalactia and bovine pleuropneumonia, sewage organisms A, B and C, the virus of vaccinia (125-175), sheep pox, canary pox, venereal lymphogranuloma, rabbit fibroma, herpes (100-150) and infectious ectromelia, "fixed and street" strains of rabbit virus, the virus of pseudorabies (100-150), Borna disease, influenza both human and swine (80-120), Newcastle disease, vesicular stomatitis (four strains, 60-100), Rous sarcoma (70-100), Fujinami myxosarcoma (75-100) and fowl plague (various strains and cultures, 60-150), various bacteriophages (30-90), the virus of Rift Valley fever (23-35), equine encephalomyelitis (20-35), rabbit papilloma (25-35) and St. Louis encephalitis (20-30), bacteriophages including typhoid III (20-30), hemocyanin crystallized (18-28), the virus of yellow fever (17-27), louping ill (15-20), tobacco mosaic (several strains, 10-27), poliomyelitis (8-17) and foot and mouth disease (7-16), bacteriophages S. 13 and *Phytomonas pruni* (8-12), edestin crystallized (6-9), pseudoglobulin (horse [6.9]), serum albumin (horse [5.4]), oxyhemoglobin crystallized (horse [5.6]), oxyhemoglobin (sheep and monkey [5]) and egg albumin crystallized (4.3). The virus particles thus grade down nearly to large protein molecules in size.

This handbook is a closely knit condensation of a great mass of highly technical papers in many controversial fields. It will be of great service to all workers in those fields as well as all others desiring an insight into one of the most complex but significant fields of investigation of the invisible pathogens of bacteria, plants and animals.

Anatomy of the Human Lymphatic System. By H. Rouvière, Professor of Anatomy at the Medical Faculty of Paris, France. A Compendium translated from the original "Anatomie des lymphatiques de l'homme" and rearranged for the use of students and practitioners. By M. J. Tobias, Assistant Radiologist, Montefiore Hospital, New York. Cloth. Price, \$4. Pp. 318, with 129 illustrations. Ann Arbor, Mich.: Edwards Brothers, Inc., 1938.

This book can be strongly recommended to physicians, surgeons and students on two counts: (1) its intrinsic merit and (2) the fact that it represents a method by which valuable books in small editions may yet be inexpensive—it is printed by photolithograph from typescript. Exact knowledge of the lymphatic vessels and of the nodes to which they lead is essential for diagnosis, prognosis and treatment of cancer and of infectious diseases. While our textbooks of anatomy have presented the facts with increasing thoroughness during recent years, Rouvière's book, devoted exclusively to the anatomy of the lymphatic system, is of great additional value because of its greater detail and its more extended report of recent work by Aagaard, Bartels, Bourgety, Gabrielle, Most, Rouvière and others. This is a translation of Rouvière's book but it is also a rearrangement of the entire text. The facts of direct application appear in the text. Matters of historical or theoretical interest are placed in a glossary at the end with appropriate references. The text represents not only careful study of the literature (768 authors) but also much original work by Rouvière and his pupils done to fill gaps or solve conflicts. The 129 illustrations of Rouvière are reproduced faithfully. An excellent index facilitates reference to any particular region. The form is good. The typescript has permitted logical and thorough paragraphing and underlining, which help in rapidity of comprehension, and the relatively low price will be welcomed by students and many others.

Berengario da Carpi. Da Vittorio Putti. Saggio biografico e bibliografico seguito dalla traduzione del "De fractura calvae sive cranei." Classici italiani della medicina, III. Boards. Price, 100 lire. Pp. 352, with illustrations. Bologna: L. Cappelli, 1937.

The city of Carpi for more than three centuries has been proud of the anatomist and surgeon Giacomo Berengario. There is considerable doubt of this name, but investigation of documents has shown that Berengario Da Carpi was Giacomo Bariogazzi. He was born about 1460. He had his first lessons in surgery from his father, Faustino, a surgical barber. During his early years he assisted his father in many difficult operations with successful results. Berengario became involved in politics and opposed the duke of Ferrara, which resulted in several severe penalties, including his exile from Carpi.

He graduated from the University of Bologna in 1489. He learned a great deal from his famous teachers Girolamo Manfredi and Leonello dei Vittori of Faenza. What occurred to Berengario during the years from 1489 to 1500 is completely unknown. During the political wars of the time he acquired considerable experience and fame as a surgeon. During the invasion of Italy by Charles VIII of France, an unprecedented epidemic of syphilis swept the country. He attained great fame by the use of mercurial ointment, of which he was neither the inventor nor the first user.

For political reasons, in the year 1517 he was confined to Bologna, where, because of his great ability, he became a teacher of surgery in the university. In 1514 Berengario published his first book, "L'edizione del Commento a Mondino," an accumulation of his anatomic and clinical experience, a voluminous and expensive book. The following year he published a compend of the same book, "Isagoge," which met with great success. He became well known and also wealthy at this time for his exploitation of a personally made "human unguentum."

In March 1517 he was called in consultation to attend Lorenzo dei Medici, duke of Urbino, for a compound fracture of the skull, from which the patient made a complete recovery. This gained him greater fame. Two months later Berengario wrote his memorable monograph on skull fractures, "De fratura cranei." This book above all else contributed to his everlasting fame; it was dedicated to Lorenzo dei Medici. In the subsequent years Berengario was called in frequent consultations in the illnesses of the Italian nobility. The pope frequently called on him to administer aid to the higher clergy, for which he received many valuable gifts, including St. John in the Desert, painted by Raffaelli.

He was very vain and throughout his life numerous comical incidents arose, notably one with Benvenuto Cellini. After all his professional achievements and financial success, he was exiled from Bologna for unknown reasons. He again returned to Carpi, where the duke of Ferrara, who in his younger days had exiled him from Carpi, now became his intimate friend and made him surgeon for the ducal court.

These repeated social, political and professional changes show that the life of Berengario was a conflict of adversity and opportunity. He died about Nov. 24, 1530, in Ferrara. No evidence has ever been found as to where he was buried.

Principles of Medical Statistics. By A. Bradford Hill, D.Sc., Ph.D., Reader in Epidemiology and Vital Statistics in the University of London (London School of Hygiene and Tropical Medicine), London. Second edition. Cloth. Price, 6s. Pp. 189, with 9 illustrations. London: Lancet Limited, 1939.

The second edition of a book of this nature appearing only two years after the first is evidence of the demand for a simple presentation of statistical methods which can be utilized by scientists and medical men. Few changes have been made from the first edition, although a useful chapter on calculation of standardized death rates has been added. Otherwise the changes are confined to clarifying the presentation in a few places.

Annual Review of Physiology. Volume I. James Murray Luck, Editor. Victor E. Hall, Associate Editor. Published by the American Physiological Society and Annual Reviews, Inc. Cloth. Price, \$5. Pp. 705. Stanford University P. O., California: Annual Reviews, Inc., 1939.

Critical reviews of scientific and medical subjects are becoming increasingly common and are serving the useful purpose of integrating the vast amount of original research work undertaken in this country and throughout the world. This first annual review of physiology is one of the newest works of this type. Its editors, confronted by the enormous dimensions of investigative work in the field of physiology, have chosen to advise the authors to attempt a critical appraisal of the contemporary field by an analysis and interpretation of the most significant contributions rather than a more comprehensive review. The result has been a series of articles on the different aspects of physiology, including growth, energy metabolism, peripheral circulation, muscle, blood and the autonomic nervous system, which in the main constitute well condensed comments on the more important advances in these fields. The bibliographies at the end of each section are well chosen, though from the nature of the case no two authorities would select exactly

the same investigations as worthy of citation. The book fills a void which has long remained unoccupied. It may be sincerely hoped that the success which attends it will be such as to encourage the editors and publishers to continue with an annual review of physiology.

Ergebnisse der Vitamin- und Hormonforschung. Herausgegeben von E. Mellanby und L. Ruzicka. Band II. Bearbeitet von G. Bertrand et al. Cloth. Price, 34 marks. Pp. 520, with 85 illustrations. Leipzig: Akademische Verlagsgesellschaft M. B. H., 1939.

The second volume of this annual publication includes seven articles by prominent investigators. May Mellanby and J. D. King discuss the relationship between dental caries and nutrition, with particular reference to the vitamins. Hans Brockmann describes the chemistry and Erick Rominger the physiology and pathology of the D vitamins. The chemistry of ascorbic acid is described by W. N. Haworth and E. L. Hirst. There is a brief chapter, written by Gabriel Bertrand, on the physiologic importance of manganese and other elements contained in animal organisms in minute amounts. J. W. Cook describes the chemistry and biologic properties of the carcinogenic substances, and Antoine Lacassagne writes on the possible relationship between the sex hormones and the production of cancer. There is an interesting chapter on the chemistry and physiology of insulin, the chemical portion being written by V. Delefeu and the physiologic portion by B. A. Houssay. A. J. Haagen-Smit writes on the physiology and chemistry of growth hormones for plants. There is a short article by Paul Karrer on the chemistry of the flavins. V. Korenchevsky writes about the bisexual and other effects of pure male sexual hormones on females. The book contains an index of investigators mentioned in the text and also a subject index to both volume I and volume II. It is indispensable for all desiring a summary of important contributions to our modern knowledge of the vitamins and hormones.

Control of Conception: A Clinical Medical Manual. By Robert Latou Dickinson, M.D., F.A.C.S., Senior Consultant Birth Control Clinical Research Bureau. Medical Aspects of Human Fertility Series Issued by the National Committee on Maternal Health. Second edition. Cloth. Price, \$3.50. Pp. 390, with 128 illustrations by the author. Baltimore: Williams & Wilkins Company, 1938.

Most recognized authorities acknowledge that the first edition of "Control of Contraception" is one of the most satisfactory and able presentations on this vital subject. It is safe to say that this book has played a prominent part in the education of physicians and their patients in the practice and theory of contraception. In general plan and scope the second edition is similar to the first. Its contents are far more extensive, however, owing to the abundant scientific contributions in the past few years. Though no radical advances have been made in the accepted views on contraception, our knowledge on this subject is more complete and on a sounder basis. Dr. Dickinson has incorporated in his book the newer work together with his considerable clinical experiences. Some of the recent advancements in reproductive physiology are also included in the appropriate sections. A most valuable feature of the book are the drawings executed by the author. These are more numerous than in the first edition and are helpful in illustrating the practical phases of therapeutic contraception. The anatomy of the male and female sex organs and the anatomy of coitus are admirably detailed and highly instructive. This book is recommended to physicians who are called on to advise on contraception. It is authoritative, conservative and comprehensive.

Le corps jaune: Étude biologique, clinique et thérapeutique. Par H. Simonnet, professeur à l'École nationale vétérinaire d'Alfort, et M. Robey, interne des hôpitaux de Paris. Préface de L. Portes. Paper. Price, 50 francs. Pp. 172, with 19 illustrations. Paris: Masson & Cie, 1939.

The literature on the endocrine functions of the ovary has accumulated to such great proportions in the past decade that the authors felt a definite need for the publication of monographs on the component hormones of this organ. Simonnet has already published a review on estrogenic substances. This monograph on the corpus luteum is considerably less voluminous. It is divided into two portions, experimental studies and clinical studies, each of which contains several chapters on various phases. The anatomy, chemistry, pharmacology and physiology

of the corpus luteum are discussed in the first portion in a comprehensive and concise manner. A large percentage of the literature is abstracted and presented systematically and clearly. The clinical section contains descriptions of assays for the corpus luteum hormone, pathologic changes in both anatomy and physiology and the therapeutic application of progesterone. This section is somewhat less authoritative than the first, especially in the chapter on therapy. This may be due to the present lack of information in this field, but actually it appears that the authors are not very critical of the reported clinical results obtained with progesterone. Their conception of the indications for such therapy is also somewhat unsound. On the whole, however, this monograph is a competent review of this very specialized subject.

Nedostatnist krovooblogy. Zbirnik prats konferentsiy z nedostatnosti krovooblogy, sklikanoy v. m. Kievi, z 21 po 23 grudnya 1936. Insuffisance de la circulation. Travaux de la conférence de l'insuffisance de la circulation tenue à Kiev le 21-23 décembre 1936. Paper. Price, 11 krb. Pp. 345, with illustrations. Kiev, Vydavnistvo Akademii Nauk URSR, 1938.

This volume contains papers presented before the Conference on Circulatory Failure held in Kiev Dec. 21-23, 1936. The paper by the clinician M. D. Strazhesko dealing with controversial problems in circulatory failure and one by the physiologist L. A. Orbeli on the nervous control of the circulation reflect thorough knowledge of the subject and make interesting reading. The text is in Ukrainian and French. The volume should prove of interest to cardiologists.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Insurance: Chronic Alcoholism as Permanent and Total Disability.—Specified benefits were payable under an insurance policy if the insured became "physically or mentally incapacitated so as to be wholly and permanently unable to engage in any occupation or profession or to perform any work whatsoever for compensation, gain, or profit." In an action on the policy, instituted in February 1937, the trial court gave judgment for the insured and the insurer appealed to the Court of Appeals of Maryland.

The principal question before the court seemed to be whether the benefits provided in the policy for total and permanent inability to work were payable in event the disability sustained by the insured ceased prior to the institution of the suit for their collection. The evidence showed that the insured began to drink, immoderately, intoxicating liquor. The habit continued until he became a dipsomaniac. His condition became progressively worse, notwithstanding medical care and attention and restraint and the treatment of specialists in sanatoriums. On April 5, 1936, he became dangerously ill of chronic alcoholism. Medical attention was required and he was confined to bed. After a slight improvement, he became worse and was sent on May 19 to a local hospital for restraint and hospitalization. He remained there until June 25, when he was taken to his home in the care of a special nurse and there received medical attention until July 9, when notwithstanding all precautions, he resumed his drinking and his condition became so grave that he was then removed to a sanatorium, where he remained until his condition improved sufficiently to enable him to be released. He left the sanatorium November 20 and returned to work. After this date, the claimed total and permanent nature of the disability ended. It therefore did not exist at the time action was instituted on the policy in February 1937.

The word "permanently," the court said, was used in the policy in its relative signification of not being temporary but lasting indefinitely, so that the disability meant was the defined condition or state which would continue indefinitely without change and without reasonable grounds to anticipate an appreciable termination. But the parties to the contract, the court

continued, contemplated the probability that the physical or mental incapacity of the insured might end after he had rightly received consecutive payments of income under the agreement during a period in which it was not reasonably anticipated that his requisite disability would end at an appreciable time. The insurance policy specifically provided that the continuation of the payment of the benefits depended progressively in time on the future continuation of the subsisting period of current disability. It provided that "if it shall appear at any time that the insured is no longer totally and permanently disabled" no further benefits were to be paid. Thus by the clear import of the provisions of the policy the phrase "permanently unable" did not mean, when read in connection with the context, that the disability of the insured must endure until his death. The court held therefore that the fact that the disability had ceased did not preclude the insured from recovering the benefits for the period when he was disabled. Whether or not the insured was totally and permanently disabled within the meaning of the policy was a question properly submitted to the jury.

In the opinion of the court, there was no evidence to justify a finding that the chronic alcoholism of the insured was the result of his conscious purpose or design. On the contrary, the testimony tended to show that he had vainly tried to restrain and control his desire but a weakness of will and of character produced by the disease caused him to yield to the temptation of an overmastering appetite for intoxicating liquor. The drinking in the first stages was voluntary but there was no testimony that the drinker was then aware of the latent danger in his habit. While his consumption of alcoholic beverages was a voluntary act, yet his ignorance of its insidious effect did not make the act a voluntary exposure of himself to the unapprehended and unexpected danger of the disease of chronic alcoholism. The disease therefore may not be considered to have been self inflicted.

The court could find no reversible errors in the record and the judgment of the trial court for the insured was affirmed.—*New England Mut. Life Ins. Co. of Boston v. Hurst (Md.)*, 199 A. 822.

Optometry: Injunction to Restrain Unlawful Practice; Contract Practice of Medicine Not "Private Professional Practice."—The purpose of this proceeding was to enjoin the defendants from the practice of optometry in the state of South Carolina. The defendants, Ritholz and certain others, partners, doing business in the state of South Carolina under the name of National Optical Stores Company, were engaged in the business of fitting and selling eyeglasses to the general public. They had physicians examine the eyes of prospective customers. These physicians maintained their offices as a component part of the store rooms or offices of the defendants and were guaranteed by the defendants at least forty persons for examination every week. If that many persons, at \$1 for each examination, was not forthcoming the defendants made up the cash deficit to the physicians in whose offices the shortage occurred.

The plaintiffs were (1) the members of the South Carolina Board of Examiners in Optometry, (2) the South Carolina Optometric Association and (3) certain individual optometrists licensed to practice in the state, who brought action on behalf of themselves and all other persons similarly situated. The complaint alleged (1) that the defendants were practicing optometry unlawfully, (2) that they unlawfully advertised the sale of eyeglasses in a manner calculated to mislead and deceive the public and (3) that they furnished to the general public, for compensation, examinations of the eyes to determine the types of glasses needed, using for that purpose doctors of medicine who hired out and sold their medical skill to the defendants. The complaint alleged further that such conduct on the part of the defendants resulted in irreparable damage to the plaintiffs and to all licensed members of the optometric profession and was detrimental to the public.

The common pleas circuit court of Richmond County granted a temporary injunction and referred the cause to a master to hear the case on its merits and report to the court the testimony taken, together with his findings on issues of law and of fact. The defendants then appealed to the Supreme Court of South Carolina.

The authorities are in conflict, said the Supreme Court, as to whether optometry is or is not a learned profession. In South Carolina, however, the legislature had placed the practice of optometry on a parity with the practice of the professions charged with important duties to the general public. The rights of persons licensed by the state to practice optometry are, therefore, property rights which a court of equity will protect by preventing encroachment on them. The jurisdiction of a court of equity to protect such rights is not displaced by the fact that the wrongs complained of are accompanied by violations of the criminal law or in themselves constitute such violations. The defendants' theory that the criminal provisions of the optometry practice act afford an adequate remedy at law and so deprive a court of equity of jurisdiction to enjoin the defendants' activities was, in the judgment of the Supreme Court, untenable. The use of the criminal courts for the redress of private and civil wrongs is generally to be deprecated. Moreover, such use of criminal process would afford only an ineffectual remedy in cases such as that now before the court.

The optometry practice act of South Carolina exempts from its requirements physicians who are duly licensed to practice in the state, so long as they practice "in the due course of their private professional practice." Any suggestion, however, that the defendants were not engaged unlawfully in the practice of optometry, because the persons whom they employed to make examinations of the eyes of prospective customers were licensed physicians, duly exempted from the requirements of the optometry practice act, was completely answered, said the Supreme Court, by the finding of the circuit court that the physicians serving the defendants were not practicing "in the due course of their private professional practice" but were acting as the agents and servants of the defendants. If such a course were sanctioned, the result would be that corporations and business partnerships might practice law, medicine, dentistry or any other profession by the simple expedient of employing licensed agents. If this were permitted, professional standards would be practically destroyed, and professions requiring special training would be commercialized, to the public detriment. The ethics of any profession are based on personal or individual responsibility. One who practices a profession is responsible directly to his patient or his client and hence cannot properly act in the practice of his vocation as an agent of a corporation or business partnership whose interests are necessarily commercial in character.

The appellants contended in their argument that the plaintiffs were without capacity to institute this proceeding. They claimed that the board of examiners was merely an administrative board, without authority to institute such a proceeding, and that the proceeding could be maintained only in the name of the state. But, said the Supreme Court, since the court held that the purpose of the act was the protection of the private property rights of optometrists, manifestly the state was not a proper party to the proceeding. Even if the defendants were correct in their contention that the proceeding could not be maintained by the board of examiners or by the South Carolina Optometric Association, an eleemosynary corporation, certainly the individual optometrists who appeared as plaintiffs in the proceeding had full capacity to bring and to maintain the suit.

The Supreme Court affirmed the order of the circuit court enjoining the defendants from the illegal practice of optometry.—*Ezell et al. v. Ritholz et al. (S. C.)*, 198 S. E. 419.

Society Proceedings

COMING MEETINGS

American Association for Thoracic Surgery, Los Angeles, July 5-7. Dr. Richard H. Meade Jr., 2116 Pine St., Philadelphia, Secretary.
Idaho State Medical Association, Boise, Aug. 23-26. Dr. J. N. Davis, 204 Fourth Avenue East, Twin Falls, Secretary.
National Medical Association, New York, Aug. 15-19. Dr. John T. Givens, 1108 Church St., Norfolk, Va., General Secretary.
West Virginia State Medical Association, White Sulphur Springs, July 10-12. Mr. Joe W. Savage, Public Library Bldg., Charleston, Executive Secretary.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1929 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. * Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

- Basal Metabolism and Preformed and Total Creatinine in Urine of Seventy Children. C. C. Wang, Cincinnati.—p. 838.
- Circulatory Function in Anemias of Children: III. Alterations in the Electrocardiogram. C. G. Parsons, Birmingham, England, and F. H. Wright, New York.—p. 851.
- Emphysema of Portion of Lung in Early Months of Life. R. M. Overstreet, Portland, Ore.—p. 861.
- Dental Caries Among Eskimos of the Kuskokwim Area of Alaska: I. Clinical and Bacteriologic Findings. T. Rosebury and L. M. Waugh, New York.—p. 871.
- Public Responsibility for Safeguarding the Health of Children. Martha M. Eliot Washington, D. C.—p. 916.

Serum Calcium in the Newborn.—Denzer and his associates determined the calcium level in the cord blood and the blood calcium curve of ninety-one newborn infants. There was a distinct drop in the calcium level of the blood during the first four days of life, with a subsequent slow rise to a point slightly above the average level of later infancy. This depression of the calcium content was not related to race, weight at birth or neonatal loss of weight. The inorganic phosphorus content of the blood during the neonatal period was higher than the phosphorus content of the cord blood, but no definite constant curve was shown. The protein level of the blood remained constant during the neonatal period and therefore cannot affect the level of the available ionizable calcium. The data derived from a comparison of calcium and phosphorus curves in the neonatal period do not supply an adequate explanation of tetany of the newborn.

- Causality and Treatment. H. H. Aptekar, New York.—p. 387.

Bereavement and Mental Disease.—Barry determined the proportion of maternal to paternal bereavements in relation to mental disease. Records were obtained from Greystone Park for 549 (white) psychotic persons, 306 male and 243 female.

All patients studied were admitted to the hospital for the first time between the ages of 16 and 25. An incidence of 15.7 per cent of maternal bereavements during childhood was found among the 549 young patients. This may be compared with 5.3 per cent of maternal bereavements, which is the median percentage reported for several control groups of normal individuals of the same ages. The incidence of paternal bereavements among the patients was 11.1 per cent, which is substantially the same as the median percentage of the normal control groups (10 per cent). The ratio of maternal to paternal bereavements was markedly higher in the psychotic patients studied than in several control groups. The author believes that the method of contrasting maternal and paternal bereavements has sufficient theoretical importance to warrant more extensive application.

American Journal of Pathology, Boston

- Study of Normal and Rachitic Bone Structure by Microphotographic Methods. L. Siegel, R. M. Allen, Grace McGuire and K. G. Falk.—p. 273.
- Carcinoma of the Pancreas.**—In 6,050 necropsies on persons more than 1 year of age D'Aunoy and his associates found forty cases of primary carcinoma of the pancreas. Males and females were represented in the proportion of 7:1. Twenty-three of the patients were more than 60 years of age. The average duration of illness was four and one-half months. Thirty-one of the neoplasms were situated in the head and nine in the tail of the pancreas. All were columnar cell carcinomas. Carcinoma primary in the head of the pancreas readily invaded the duodenum and that primary in the tail of the pancreas spread over the peritoneum. Metastases in the liver were observed in twenty-five instances.

Acute Transient Intestinal Atony. — Oppenheimer describes a peculiar disorder of the intestinal tract and states that in a number of patients referred for x-ray examination, because of some clinically obscure abdominal condition, an excessive enlargement of the colon was found roentgenologically and was reported as megacolon. For reasons of their own, the clinicians did not accept this diagnosis and the examination was repeated after three or four days. On this occasion, as well as on numerous other reexaminations during the subsequent twenty-eight months, the colon was found to be perfectly normal. In one case no clinical diagnosis could be made, in two others a diagnosis of mesenteric thrombosis was adopted on clinical grounds and in three the presence of renal calculi was demonstrated by x-ray and urologic examinations. Any technical mistake that might supposedly be responsible for the singular enlargement was excluded. In the foregoing cases most of the clinical symptoms and signs were variable and inconstant, but one symptom, acute and severe colicky pain, was present in all of them. From a study of these cases and a comparison of many patients suffering from severe pain the author concludes that acute atony of the colon, the stomach and parts of the small intestine, with spasm of the pylorus and of some intestinal loops, occurs as a result of either spontaneous or artificial irritation of the urinary tract, in disease of the gallbladder and in other types of colic. The rapid disappearance of this atony proves that the intestinal muscle itself is not damaged. This confirms the results reported by Alvarez, who found that in experimental paralytic ileus the excised intestinal muscle responds normally to stimulation. Paralysis of the intestine, whether transient or persistent, may be produced by inhibitory impulses acting on the digestive tract. Alvarez showed that this inhibition may be produced by irritation of the peritoneum, and the author's observations prove to him that it may originate also in extraperitoneal organs such as the renal pelvis. This observation explains also the fact that urinary disorders often induce gastrointestinal symp-

toms even when there is no question of uremic poisoning. From the practical point of view it is important to know that megacolon, as well as gastric and intestinal disorders, can be simulated roentgenologically and that, roentgenologically, functional disorders may resemble actual anatomic changes, especially as regards the digestive tract.

Radiation Pneumonitis.—McIntosh and Spitz studied the underlying pulmonary changes in sixty patients with mammary cancer who received roentgen irradiation. Radiation pneumonitis was found in some degree in thirty-six. Observations are based on correlations between pulmonary tissue doses and x-ray appearance and available necropsy material. Kilovoltage higher than 200 kilovolts (peak) was not used. Pulmonary changes are found in proportion to the amount of radiation received in the lung, except that the lungs of elderly persons with arteriosclerosis are especially prone to pneumonitis and permanent fibrosis. In women less than 60 years of age, unless showing premature senility, pulmonary tissue dosage of less than 3.5 threshold erythema doses through any considerable part of the treated lung rarely produces changes demonstrable roentgenologically. The milder grades of roentgen pneumonitis are symptomless and clinically insignificant. Of fifteen patients with severe roentgen pneumonitis ten had symptoms, usually cough and dyspnea, found chiefly from two to six months after treatment. In only two cases did genuine discomfort from cough persist beyond this time. Five patients had short bouts of clinical bronchopneumonia at the height of their pulmonary reaction, with recovery in all. Only one had a second attack, a patient more than 80 years of age. Irradiation pneumonitis and pulmonary metastasis must be differentiated because if metastasis is present palliative treatment may be indicated, but if pneumonitis is present more treatment is obviously undesirable.

Painless Closure of Surface Wounds.—Gosis outlines a method of closing superficial wounds without pain. When there is no coexistent laceration of muscle or deep fascia, the skin surrounding the wound is cleaned of any foreign matter, washed with soap and water and wiped dry. After this, compound tincture of benzoin is painted on the skin and permitted to dry. Flaming the adhesive tape will allow it to adhere to the painted skin for at least ten days without irritation or loosening. Strips of adhesive tape are cut about one-half inch wide and long enough to project about three-fourths inch beyond the ends of the wound. If the wound is large and gaping, a wider piece of adhesive tape is used. The adhesive strips are placed on the prepared skin, about one-fourth inch away from the edges of the wound and as parallel to them as possible. The strips are then sutured together with surgeon's silk or any household thread of suitable strength. As each bite is taken and drawn tight, the edge of the adhesive tape through which the suture

was just passed is gently pressed down with the fingertip or thumb forceps. This prevents slipping and avoids the necessity of keeping the suture continually on tension. As the thread is drawn tight, the wound edges approximate by themselves. With practice, inversion of the edges is easily avoided. It is best to leave no elevation of the adhesive tape near the wound for insertion of the needle and thread. A thin curved cutting edge needle is simply slipped between the skin and the superimposed adhesive tape. When sharp angles or corners of tissue must be approximated, it is best to apply preliminary strips of tape at the angle of the wound. A suture or two through these will fasten the angles of the laceration in proper position. After that, strips are applied as previously described and sutured in the usual manner. This method, the author points out, promotes wound healing in cases in which gross infection has not occurred at the time of injury by lessening the amount of additional trauma inflicted on a wound by penetrating sutures. Should infection ensue, there is no obstacle to self drainage. The sutures are removed without any pain.

Treatment of Amenorrhea of Endocrine Origin.—Livingston and his colleagues used estrogen in the treatment of thirteen cases of amenorrhea. Bleeding and enlargement of the uterus with improvement in secondary sexual characteristics was produced in every case. One patient became pregnant, while under treatment, after eight months of amenorrhea. Four patients continued to menstruate after treatment was discontinued, and one of these subsequently became pregnant after three years of sterility. The gonadotropic substance was used in five cases of amenorrhea, and bleeding occurred in three. One of these three later became pregnant. Dilatation of the cervix to produce menstruation through pituitary stimulation was successful in the two cases in which it was attempted. One of these patients subsequently became pregnant after twelve years of sterility.

Trichomonas Vaginalis Vaginitis.—Zener supplements the report (abstracted in THE JOURNAL, March 13, 1937, page 921) of the vioform (iodochlorhydroxyquinoline) treatment of *Trichomonas vaginalis* vaginitis. He has treated a total of 106 cases and obtained cures in 98.1 per cent. A number of cases which tend to substantiate the theory of rectal origin of the disease are reported. A routine of treatment which the author is now using is not only directed at the vaginitis but also eradicates the organism from the rectum, thereby reducing recurrences to an absolute minimum. 1. Vioform powder insufflations are given at least three times a week, as therapy for the vaginitis. 2. Vioform is given orally in dosage of four 4 grain (0.26 Gm.) tablets daily in order to eradicate the rectal infestation. The basis for this therapy is the excellent results obtained by David and others with vioform in the eradication of parasitic infestations of the intestinal tract.

Action of Soap on Skin.—In determining the cutaneous action of soap, Blank performed patch tests with various pure and mixtures of fatty acids. Saturated fatty acids of low molecular weight yield a much higher percentage of positive reactions to patch tests than do acids of higher molecular weight. Persons with normal skin give positive reactions to fatty acids of low molecular weight as frequently as do persons with pathologic changes of the skin. Fatty acids of a molecular weight higher than that of capric acid produce reactions somewhat less frequently on normal than on skin with pathologic

changes. Positive reactions to unsaturated oleic acid occur about as frequently as do positive reactions to saturated acids of high molecular weight. Certain fatty acids give a more intense reaction when maintained at a pH of 7 than at a pH of 5. Diminished reactions at a pH of 3 have also been observed. It is proposed that neither the alkali nor the fatty acid alone is responsible for the irritation produced by soap but that each is a contributing factor and that the higher the molecular weight of the fatty acid, the more alkali will be required before irritation results. In 150 cases of contact or atopic dermatitis a mixture of 25 per cent sulfonated mixed olive and teaseed oils, 25 per cent liquid petrolatum and 50 per cent water, which has a pH of approximately 6.5, has been substituted for soap. Most of these patients have found this mixture a satisfactory detergent. Irritations followed the use of the material in less than 10 per cent. In eighteen cases in which there were remissions with the use of the oil mixtures, relapses occurred when soap was again used.

Allergic Dermatitis Simulating Lymphoblastoma.—Cannon discusses eight cases, of a group of about eighty, that he has followed closely. These patients suffered from a condition which closely simulated the lymphoblastoma group of diseases but which was considered after careful study to be of different origin. The disease was in all cases of many years' duration and had been variously diagnosed, both clinically and histologically, by prominent dermatologists, as mycosis fungoides, leukaemia cutis and Hodgkin's disease. Beginning in every instance as a simple dermatitis suggestive of an allergic reaction, the condition progressed through cycles of cutaneous thickening, exfoliation and lichenification to the formation of plaques and tumors resistant to all the usual forms of treatment. An examination of the patients not only by the usual clinical and laboratory methods but also in relation to their environment, antecedents and social and economic situation led the author to believe that the condition was not a malignant process or even a nonmalignant disease entity but a simple cutaneous inflammatory phenomenon of allergic origin. This belief, he says, was further confirmed by the striking response that occurred when the patients were removed from their previous environment and also when known irritants were eliminated. The condition in question can be differentiated from the malignant diseases of the lymphoblastoma group by systematic clinical and microscopic studies and proper correlation of results.

Mussel Poisoning.—Gibbard and his associates state that specimens of mussels and clams have been collected from various localities during the past season. The objective was to determine whether or not mussels become toxic and whether or not poisonous mussels are confined to any definite localities. To date about 200 collections have been made. Poisonous shellfish have been received from only one main area in Nova Scotia, Digby Neck. This poison is similar to the poison found in California mussels and in all probability is at least closely

related to if not identical with the mussel poison described by Meyer and his co-workers. Two species of mussels, *Mytilus edulis* and *Modiola modiolus*, have been found to be toxic. So far as can be learned the latter species of mussel has not been previously incriminated in human outbreaks of mussel poisoning.

Testosterone Propionate for Dysfunctional Uterine Bleeding.—The Mazers used androgen in the treatment of thirty-eight women with menstrual disorders. Twenty-nine of the patients had metrorrhagia for periods averaging twelve weeks with a minimum of four weeks, and nine had menorrhagia for an average period of seventeen months with a minimum of four months. The patients were given testosterone propionate in sesame oil intramuscularly three times a week for from two to nine weeks. The individual dose varied from 2.5 to 25 mg. A cure was considered to have been effected if the abnormal bleeding ceased during the period of treatment and did not recur for at least four months after treatment was stopped. The follow-up period ranged up to nineteen months with an average of eight months. Patients who were only improved are considered not cured. By these criteria, twenty-six of the thirty-eight patients were cured and twelve were only temporarily or not at all improved by the therapy. No constitutional or local ill effects were encountered by any of the thirty-eight patients. The menstrual rhythm of the thirty patients who were menstruating regularly prior to the onset of the abnormal uterine bleeding was not disturbed. There was no obvious tendency toward a reduction of fertility by the doses employed, as four of the patients conceived within one to ten months after the withdrawal of treatment without a tendency to abortion. Three of the patients were delivered of normal infants and one had an induced abortion. The menopausal symptoms complained of by a number of patients were not influenced by the doses employed. The possibility of evoking masculine characteristics with the use of large doses of testosterone over a long period of time must be borne in mind. A tendency to virilism, though mild and temporary, was shown by four patients who were treated with large doses of testosterone for other conditions than dysfunctional uterine bleeding. Two of the four had an apparent increase of facial hair. The other two, girls of 14 years, had a definite decrease in the pitch of the voice.

Testosterone Propionate in Eunuchoidism.—According to Hoskins and his co-workers the daily intramuscular injection of 25 mg. of testosterone propionate for periods of from nine to fourteen days brought about rises in the urinary androgens of four eunuchoids from basal levels of from 2 to 16 international units a day to from 44 to 115 international units a day and of urinary estrogens from the equivalent of 0.3 to 5 micrograms of estrogen a day to that of 5 to 15 micrograms of estrogen. This constitutes a restoration to normal values for both groups of substances. Both androgen and estrogen values fell toward pretreatment levels when medication was stopped. The changes in androgen and estrogen excretion paralleled the physiologic

effects of testosterone propionate in the organism. Of three patients for whom the cause of the hypogonadism was unknown the extent of recovery of administered testosterone was 65, 49 and 49 per cent respectively, on the assumption that half of the excreted material by weight is androsterone and half dehydroandrosterone. The recovery was 20 per cent for a patient whose pituitary was damaged by a suprasellar cyst. The rise in urinary estrogens to normal values following the administration of androgen suggests that the urinary estrogens of normal male urine may be derived in part from the metabolism of the testis hormone. However, the increase in the excretion of estrogen represents only 0.06 per cent of the androgen injected.

- *Diabetes, Insulin Action and Respiratory Quotient. E. M. Bridge and Eleanor A. Winter, Baltimore.—p. 257.

Diabetes, Insulin Action and Respiratory Quotient.—Bridge and Winter tried to correlate the action of insulin with the blood sugar and the respiratory quotient in diabetic subjects. The study shows that the respiratory quotient of regulated diabetic patients bears no consistent relation to the intensity of the insulin effect as measured by blood sugar. Hypoglycemia may occur while the respiratory quotient is high, average, stationary or falling. A constant or decreasing respiratory quotient at a normal or moderately low level may be found during periods in which the blood sugar rises to high diabetic levels; no time relationship was apparent between the respiratory quotient and the trends toward frank diabetes. The observations cannot be reconciled with the view that insulin acts as a specific stimulus to carbohydrate combustion. At present, control of the blood sugar level in diabetes is often considered synonymous with control of the disease itself. Insulin and diet are adjusted with this single criterion in mind. But in the partially regulated patient hypoglycemia may indicate no more than an excessive deposition of muscle glycogen, and hyperglycemia may develop without changing that more fundamental aspect of carbohydrate physiology; viz., combustion. Since neither the intensity of the diabetic process nor the effectiveness of insulin dosage is measurable directly by blood sugar regulation, it is obvious that emphasis may be wrongly placed if the blood sugar level is considered the sole criterion of regulation. Theoretically, four aspects of carbohydrate metabolism would seem to deserve attention for judging the regulation of diabetic patients: ketosis, respiratory quotient level, conditions affecting the efficiency of insulin action and blood sugar fluctuations. It appears that the major aspect of the disturbance of carbohydrate metabolism in diabetes, which has been offered from time to time in the literature and the foregoing data affirm, is centered in the liver. The evidence for this theory comes from several sources: 1. Removal of the liver from diabetic dogs causes a rapid disappearance of the diabetic symptoms. 2. Insulin appears to influence carbohydrate combustion in diabetes only indirectly. This influence seems to be associated with changes in the glycogen content of the liver. 3. Carbohydrate combustion and respiratory quotient appear to be related to the glycogen content of the liver. 4. The overproduction of dextrose from protein, from glycogen and possibly also from fat in diabetes represents a process which is in many respects the opposite of the inability to form dextrose from these same precursors in hepatic insufficiency.

Antiseptic Value of Phenothiazine.—In the treatment of thirty-three patients with chronic and sixteen with acute infections of the urinary tract, DeEds and his colleagues used phenothiazine in average daily doses of 1.33 Gm. for an average of 7.4 days. Ten patients with acute infections of the urinary tract were permanently relieved of symptoms, and pus and bacteria disappeared from the urine. Cystoscopic examination showed an increase in the capacity of the bladder and a decrease in hyperemia of the bladder mucosa. Five patients with chronic inflammation of the urinary tract were clinically cured and twenty were improved. Several patients included in the "improved" group were "cured" as long as they remained under observation, but they failed to report during the four week period arbitrarily established as necessary before the patient was pronounced "cured." Only eight of the forty-nine patients failed to secure relief from symptoms of inflammation of the urinary tract following the administration of the drug. No undesirable effects from the drug could be demonstrated in the gastrointestinal tract, circulation, kidneys or liver. Anemia occurred in only a few cases (three) after an average total dose of 23.3 Gm., which is far beyond the usual therapeutic dose. The anemia was apparently hemolytic in nature, since there was an early reticulocyte response and a rapid regeneration of the blood, which would not have occurred if there had been injury to the bone marrow.

- *Morphine: Dangerous Drug in Chronic Asthma. R. M. Balyeat, Oklahoma City.—p. 556.

Danger of Morphine in Asthma.—Balyeat believes that morphine should seldom be used in the treatment of chronic asthma. Patients with chronic asthma, with or without bronchiectasis, have a tendency to drown in their own secretions. The asthmatic attack is nothing more than nature's means of trying to force out of the small tubes or bronchiectatic areas the tenacious and purulent secretions. Owing to the lining of the larger tubes with secretions and to the plugging of the bronchioles, it is difficult for the asthmatic person to obtain a sufficient amount of oxygen. Therefore respiration is frequently increased from the normal sixteen to twenty up to thirty or forty a minute. Morphine will partially or totally destroy the cough reflex and at the same time, acting centrally on the respiratory center, materially reduce the number of respirations. Because of the changes in the chest, the number of respirations are materially increased so as to give the asthmatic patient plenty of oxygen, and often when the number is reduced the amount of oxygen allowed to pass through the heavily lined bronchial tubes is not sufficient to sustain life. Many physicians do not carry epinephrine hydrochloride (1:1,000 dilution) with them but morphine is always in their grip. Therefore when a patient suffering from an asthmatic paroxysm is visited morphine is given. Not uncommonly asthmatic patients with a tolerance to epinephrine are seen. Under such conditions 0.5 Gm. of aminophyllin in 20 cc. of physiologic solution of sodium chloride should be given intravenously, or an equal mixture of ether and olive oil should be given by rectum. Frequently through lack of knowledge of the value of these two procedures or because of the inconvenience, morphine is given. The author reports five cases in which he feels reasonably sure that morphine was the immediate cause of death.

"Lung Abscess" and Metrazol Therapy.—Since October 1937 Zeifert has induced about 8,500 metrazol convulsions and about fifty camphor convulsions. Despite all precautionary measures an occasional pulmonary "abscess" appeared. He observed that pulmonary complications occurred only in cases in which delay occurred between the entrance of blood into the syringe and the actual injection of its contents into the vein. He proceeded to review from the roentgenologic aspect all cases of "lung abscess," and from the great similarity of the clinical pictures he concluded that the etiologic factor in all the cases was pulmonary embolism on which a process of suppurative was subsequently superimposed. Investigation then converged on the problem of determining where the emboli originated and how they were introduced into the blood stream. The blood of some patients coagulates more rapidly in metrazol solution than that of others. The author has seen small blood clots appear in the syringe within fifteen seconds after the needle entered the vein. Reinjection of such bits of clotted blood will result in embolism. He devised a method for the prevention of this complication by adding an anticoagulant to the metrazol solution. He prepared a 10 per cent solution of metrazol in a vehicle consisting of 2.5 per cent chemically pure sodium citrate in distilled water. This solution was then autoclaved and examined for any alteration. As no change was apparent, it was administered to a group of patients in the regular therapeutic dose. The usual dose produced the typical grand mal type of metrazol seizure. Apparently there was no change in the convulsive property of the metrazol or pharmacologic change as a result of the mixture of the two drugs. The author has used this anticoagulating metrazol solution for the last eight months, during which time no pulmonary complications have developed in any of his cases. Since the introduction of the anticoagulant into the convulsive solution he has induced 3,200 convulsions without a single case of pulmonary embolism or any other pulmonary complication.

Lymphocytic Choriomeningitis.—Armstrong and Sweet report two established cases of lymphocytic choriomeningitis. The finding of active choriomeningitis virus in three of five mice trapped in the homes of the patients and the failure to find the infection in twenty-one mice trapped in eight homes and buildings wherein no human cases of the disease had occurred

indicated that the association between the human cases and the infected mice is more than a coincidence. It is believed that the mice constituted the source of the human infection since: 1. In each instance the patient was ill in the home for only four days before being hospitalized. 2. The housewife in both households apparently suffered infection, while one mate escaped and the only evidence of infection in the other members of the household was a moderate degree of immunity as judged by serum-virus neutralization test. These observations suggest an exposure to infection in the home rather than a human-contact infection. 3. The capture of a less than half grown infected mouse in the home of one of the patients eighty-seven days after the patient had been removed from the house indicated the existence of an active infection in the mice independent of the presence of a recognized human case. 4. The presence in one home of a person who possessed strongly developed antibodies at a time when the patient's immunity was but partially developed suggests that the case did not constitute the initial introduction of the virus into the household. The observations suggest that gray mice, *Mus musculus*, constitute a reservoir of choriomeningitis infection from which human cases may be contracted.

X-Rays for Menstrual Dysfunctions and Sterility.—Bruck and Fruchter discuss the endocrine factors governing the normal menstrual cycle and also the endocrine imbalance in the production of menstrual dysfunctions and sterility as it is related to the pituitary and ovary. They treated 108 cases of various menstrual dysfunctions (amenorrhea, oligomenorrhea, menorrhagia and metrorrhagia) in single and married women, with and without sterility, with roentgen rays. From their summary of the results obtained they believe that they are justified in stating that, although this treatment is empirical and its mode of action is not as yet understood, it is definitely worth while and gives a fifty-fifty chance to those women in whom all other methods have been tried and found wanting. Pregnancy took place in 45 per cent of women with deficient menstruation and sterility.

Familial Acne Vulgaris Suggesting Acne Conglobata.

—It seems probable to Hellier that in many cases of chronic pyodermatic cutaneous lesions the importance of the "terrain" is at least equal to that of the infecting organism in determining the character of the eruption. He believes that the case which he reports illustrates this clearly, for, while the patient himself showed a condition allied to acne conglobata, other members of his family showed varying degrees of less severe involvement down to an apparently ordinary acne vulgaris. The patient presented acne-like pustules and scars extending over the trunk and limbs, with large infiltrated plaques on the buttocks oozing pus from fistulas, sebaceous cysts, rhinophyma and a coarse type of skin. Following the excision of a large inflammatory plaque from the buttock, a squamous carcinoma developed. The relation of this case to acne conglobata is discussed and it is suggested that the latter condition depends on the patient's reaction for its characteristic appearance rather than on the type of invading organism. Several other members of his family showed one or more of a group of symptoms, which included diminished resistance to acne organisms, a tendency to comedone formation and excessive scarring, a coarse skin and rhinophyma, sebaceous cysts and possibly mental sluggishness. It is suggested that these symptoms are dependent on some factor or factors which are inherited as mendelian dominants.

*Treatment of Acute Sprains by Procaine Infiltration (Leriche's Method). E. J. Moynahan.—p. 671.

Longevity of Oarsmen.—Hartley and Llewellyn determined the life span of 376 Oxford and 391 Cambridge oarsmen who were on the respective crews between 1829 and 1928. The actual deaths during the several periods (from 1829 to 1862, 1863 to 1893, 1894 to 1923 and 1924 to 1928) are compared with those expected according to the standard tables. In each of the periods and age groups the comparison favors the oarsmen. Thus, taking the lives as a whole, the actual numbers of deaths in the four periods were only 87.8, 76.7, 85.1 and 93.5 per cent of the expected mortality. Over the whole period of the investigation the mortality experience of university oarsmen was appreciably superior to that of assured lives of their own generation, but of later years this relative superiority has shown a tendency to diminish. The study gives no support to the idea that strenuous rowing by healthy subjects, when combined with adequate training, places any undue strain on their cardiovascular system or other organs and leads to any diminution of longevity. Looking at the figures from another angle, the mortality of oarsmen has maintained a uniform level of excellence, but the general body of assured lives has only recently approximated to this level. The oarsmen have been compared with a body of men living at the same time, insured and accepted for life insurance at ordinary rates and free from any serious blemish but probably not possessing those advantages of physical fitness and social and economic standing enjoyed by the athletes concerned. The ideal would be to compare the life-expectancy of the oarsmen with that of their fellow graduates, living at the same period and under similar conditions but not participating in such strenuous exercise.

Treatment of Acute Sprains by Procaine Infiltration.—Moynahan used a 2 per cent solution of procaine hydrochloride in the treatment of seventeen cases of sprained ankles, one of the wrist, two of the fingers, two of the thumb, two of the knee and two of the back. In every case pain and swelling were definitely decreased and the period of incapacity was considerably less than when the more usual treatment was given, confirming the results of Campbell (1938), who used Leriche's method. The procaine infiltration method has wider applications than the treatment of sprains. Leriche and Froehlich (1936) used it successfully in the treatment of certain fractures, particularly those involving a joint requiring early mobilization, as well as in dislocations, chronic effusions and many other conditions. Recently Campbell had success with it in the treatment of ankle fractures. The author found that it gives a dramatic and lasting cure of such minor annoying complaints as "stiff neck," "fibrositis," lumbago and vague muscular pains. The injection of a small quantity of procaine hydrochloride into the tender spots in the trapezius in cases of "stiff neck" results in a dramatic, almost instantaneous cure.

Addison's Disease.—Having available several cases of Addison's disease, Dryerre decided to test, under carefully controlled conditions, the claims made for the adrenocortical insufficiency test proposed by Cutler, Power and Wilder. The test was carried out on fourteen subjects. Four of these were known to have Addison's disease and five were patients suffering from some debilitating condition whose features resembled in some way or other those of adrenal insufficiency, but all were diagnosed clinically as not suffering from Addison's disease. The remaining five subjects were normal healthy control individuals. The results reveal that on the third day of the administration of a salt-poor potassium-high diet the concentration of sodium in the urine is much higher in patients with adrenal insufficiency than in control subjects. Under the conditions of the test, the concentration of urinary chlorine in patients with adrenal insufficiency did not differ from that in the control subjects with the consistency that was claimed by Cutler, Power and Wilder. The concentrations of sodium and chlorine in the blood serum of patients with Addison's disease may not differ materially from those of control subjects. Cutler, Power and Wilder state that their procedure "subjects the patient to less risk of collapse than the six-day period of restricted intake of salt heretofore resorted to for diagnostic purposes." The author states that, while this claim is no doubt correct, it is apparent that even a three-day period is not without risk, particularly with a high potassium intake. The test should not, therefore, be undertaken without due precautions. These involve the careful clinical observation of the patient throughout the test and the giving of adequate quantities of a potent cortical extract and, if necessary, saline dextrose solutions intravenously, on the first signs of the developing of a crisis.

Microsporium New to India.—Maplestone and Dey discuss the occurrence of seven cases of microsporion infection of the scalp caused by a fungus heretofore unknown in India. The clinical, microscopic and cultural characters are given. Culturally it

grows slowly and shows two types of growth—a raised faviform type and a flat type. The type of growth resembles that of *Microsporon ferrugineum*. The cultures were various shades of brown, whereas brown has only occasionally been observed in *Microsporon ferrugineum*, in which deep yellow is most usual. The morphology is similar to that of *Microsporon ferrugineum* and possibly a variant. Of seven cases recorded three were treated by the authors. The first case had multiple patches on the scalp and was treated with roentgen rays. An epilation dose was administered after the technic of Adamson. Twenty-one days after the exposure, while there was a partial epilation, a patch 2 inches in diameter was noticed behind the left ear and was treated twice daily with a preparation containing 0.65 Gm. of thymol, 0.7 cc. of oil of cinnamon and 30 cc. of mild solution of iodine. Along with this application, manual epilation was done and the patient was discharged cured in about three weeks. The second patient showed a few tiny spots and was treated with the application of the same paint along with manual epilation. He was discharged cured in a month. In the other patient a single patch on the right parietal eminence about 2 inches in diameter was treated for three months with the same preparation. About three months later with apparent continuous treatment she came back with multiple patches on the scalp. The same paint was continued for two months along with manual epilation. As the progress was slow, 2 drachms (8 cc.) of glacial acetic acid was added to an ounce (30 cc.) of the foregoing preparation. The patient was discharged cured after using this new application for three months.

Bacterium Paratyphosum C as Cause of Enteric Fever.

—Nabih records, for the first time, the isolation of *Bacterium paratyphosum C* in Egypt. He isolated it from the urine of nine patients and the feces of two patients suffering from enteric fever during the summer of 1937 and the early part of 1938. Its frequency is comparable with that of *Bacterium paratyphosum B*. Its inclusion in prophylactic vaccines, along with the usual T. A. B. vaccine is worthy of consideration.

Carcinogenic Materials in Liquid Petrolatum.—A range of commercial distillates of a topped crude Borneo, liquid petrolatum were tested by Twort and Lyth for carcinogenic activity and they found that the peak was around a viscosity at 25 C. of from 200 to 250 centipoises. The whole range of oils was biologically active. This activity had been foreseen from an examination of the physical characteristics, alone sufficient to condemn the utilization of any single representative as a lubricant when likely to come into contact with the user. A greater concentration of the carcinogenic material was obtained by molecular distillation of oils than by ordinary distillation at from 3 to 10 mm. The middle fractions of a Borneo crude oil were mostly responsible for pathologic changes in the organs—fatty infiltration of the liver and hyaline degeneration of the spleen. Pulmonary tumors were more prevalent than is usual when utilizing this type of agent for testing carcinogenicity for the skin. Their incidence was somewhat higher in the more viscous fractions but was not apparently related to their carcinogenicity for the skin.

- *Treatment of Postencephalitic Parkinsonism with Bulgarian Belladonna. F. J. Neuwahl.—p. 693.

Anginal Syndrome Due to Hypothyroidism.—Beaumont and Robertson describe a case which was originally diagnosed as angina of effort. No clinical evidence of myxedema was found, but the basal metabolism rate was —33. Under adequate treatment with thyroid extract the patient was enabled to return to work and his anginal symptoms disappeared. With either an overdosage or an underdosage of thyroid extract his symptoms recurred. The case emphasizes the fact that subtotal thyroidectomy for the relief of angina may incur the danger of increasing the symptoms unless myxedema and "masked hypothyroidism" have been excluded.

Cyclopropane "Sleep" with Nupercaine Spinal Anesthesia.—Dodd and Hunter used a combination of nupercaine spinal with cyclopropane general anesthesia in seventy major operations (mostly abdominal). The preanesthetic used throughout the series was 0.02 Gm. of pantopon, $\frac{1}{450}$ grain (0.0004 Gm.) of scopolamine and 0.85 cc. of a 25 per cent solution of pyridinebetacarboxylic acid diethylamine (coramine). The spinal anesthetic was a 1:2,000 solution of nupercaine. The general anesthetic was cyclopropane delivered through a Heidebrink continuous flow machine. Oxygen was usually necessary. The advantages of this method are the tranquil respiration, a rapid return to consciousness, the absence of nausea and vomiting during the operation and the absence of major thoracic postoperative complications. Cyclopropane tends to keep the blood pressure from falling and has no toxic effect on the liver or the kidneys. The postoperative sedative was 0.01 Gm. of morphine (or alternatively 0.005 Gm. of diacetylmorphine) and 0.85 cc. of coramine. The addition of cyclopropane "sleep" to spinal anesthesia is an undoubted improvement, a pleasant and effective anesthetic for the patient and a material aid to the surgeon in abdominal operations.

Postencephalitic Parkinsonism and Bulgarian Belladonna.—Neuwahl used an extract of Bulgarian belladonna in the treatment of 123 cases of postencephalitic parkinsonism. The results were remarkably good in the majority of cases and no relapses were recorded. The preparation has now been standardized and gave better results in its new form than the former decoction in white wine. Equally good results can be obtained if the English belladonna root is substituted for the Bulgarian. In only six cases was there a difference in action. Toxic reactions result from the administration of high doses and can be avoided by beginning with small doses and gradually increasing them until the individual's optimum is found. The treatment is contraindicated and useless in cases of chronic epidemic encephalitis. From three to fifteen months after the patients' maintenance doses were fixed and they had returned home it is found that nine are not improved, two are slightly improved, twenty-nine are moderately improved, twenty-seven are greatly improved, fifty-one are symptomatically cured, two have died of intercurrent disease and three have died of a recurrent attack of encephalitis. Fifty-five of the entire group of patients are fit for work.

Electrocardiogram in Hypertension.—Routier and Gerbeaux say that all investigators who have given their attention to the electrocardiographic aspects of hypertension have observed a left ventricular predominance, which is reflected in the electrocardiogram by a deviation of the electrical axis of the rapid wave toward the left. After reviewing the reports of several investigators, the authors describe their own observations on 300 patients, all of whom they examined clinically, roentgenologically and with the electrocardiograph. In many instances they also made a blood count, determined the sedimentation speed, the urea content and the cholesterol content of the blood, inspected the fundus oculi and made diverse functional tests of the kidney. Summarizing their observations, the authors say that in 38 per cent of the examined patients the electrocardiogram was either normal (19 per cent) or showed a simple deviation toward the left (19 per cent), but in 62 per cent there were strong pathologic changes. Of the latter group 75 per cent presented an inversion of the T wave in the first lead. In correspondence with this the silhouette shows a large, globular heart and in the cases which could be verified there was an unequal distribution of the ventricular hypertrophy; it was considerable toward the base but nonexistent at the top, where the heart appeared slender. The authors conclude that the electrocardiographic examination of the patients with hypertension is a means to explore the condition and function of the heart and of the arterial system and thus it is of primary importance in the prognosis.

*Sulfanilamide and Tuberculosis. H. Faniel, A. Jeurissen, R. Courtois and F. Dwelshauwers.—p. 725.

Sulfanilamide and Tuberculosis.—Faniel and his associates point out that although the mode of action of sulfanilamide is not completely understood as yet it is evidently active particularly against streptococci, gonococci and meningococci processes and in coccic disorders in general. Some investigations seem to indicate that the therapeutic value of sulfanilamide is the result of a specific action on the elements constituting the microbic capsule, but the substance seems to have also a certain modifying effect on the humors of the diseased organism. In this connection the authors cite the case of a young mother and her child. When the mother continued to have an elevation of temperature after her delivery she was given sulfanilamide and two days later there was a decrease. Simultaneously with this improvement in the mother, certain cutaneous symptoms in the nursing subsided and the authors suggest that the improvement in the nursing must be attributed to the modification of the maternal milk by the sulfanilamide. They think that it would be interesting to investigate whether the sulfanilamide passed directly into the milk or whether it produced humoral changes in the mother. Following remarks about the dose of sulfanilamide in relation to the body weight, the authors discuss the characteristics of the tubercle bacillus, which might play a part in its behavior toward sulfanilamide. They point out that it is encapsulated and that its capsule is particularly resistant. Since a review of the literature disclosed contradictory reports about the action of sulfanilamide on the tubercle bacillus, they decided to try sulfanilamide themselves on tuberculous patients. They found that irrespective of the mode of administration (oral, intramuscular or intravenous) it was generally well tolerated. They cite several case histories and stress that they resorted to sulfanilamide only in cases in which no other treatment was indicated. At the appearance of albumin in the urine, the administration of sulfanilamide was interrupted. Although on

the whole there were no dangerous reactions, neither can it be said that the treatment resulted in an appreciable modification of symptoms. The only advantage that could be observed was a diminution in the expectoration with a modification in the aspect of the sputum. Apparently the sulfanilamide acts on the associated micro-organisms, but it seems to have no effect whatever on the tubercle bacillus.

Arterial Air Embolism.—Three cases of arterial air embolism, all three of which developed in connection with surgical operations on the lung, induced Curtillet to study the problem of arterial air embolism. Realizing that only direct microscopic observations on living animals could solve certain problems of arterial air embolism, he made experimental studies on frogs and on the ears of rabbits. After citing some of his earlier reports on these studies, he presents in this paper a general study of the problem. He defines as arterial air embolism an accident characterized by the entrance of air into a pulmonary vessel and its transport by the blood current to the arterial regions of the systemic circulation. He disregards venous embolism. Crossed embolism, however, which, as regards its symptomatology, prognosis and therapy presents a veritable arterial embolism, he considers in this report. The author takes up the pathologic physiology and anatomy of arterial air embolism and then discusses the clinical and therapeutic aspects. In the conclusion he emphasizes that arterial air embolism has become frequent since the advancement of pulmonary surgery and artificial pneumothorax. From the physiopathologic point of view it is important to consider separately the progression of air in the large arteries, where besides the influence of the blood current it undergoes that of gravity, and in the small arteries, of which it occupies the entire lumen. The microscopic study of the air bubbles in the small vessels permits interesting observations. The bubbles do not reach the vessels of a caliber less than 30 microns; that is to say, they never reach the capillaries. Arrested in the arterioles from 30 to 40 microns in diameter, they are rapidly absorbed. The passage of the air of the arteries into the veins is effected by the arteriovenous anastomoses the caliber of which is in excess of 30 microns and thus it can be understood that the passage is possible only in the regions endowed with these channels: the members, the face, with the exclusion of the visceral regions which do not have them or at least do not have channels large enough. Without doubt it is the abnormal existence in the lung of arteriovenous anastomoses the diameter of which is in excess of 30 microns which explains the crossed embolisms developing in spite of the absence of interauricular communications. The microscope also makes it possible to specify the mode of reestablishing the circulation of the blood in the course of the progression and of the resorption of air as well as the nature of the local vascular reactions which cause the embolism. The fatal quantity of air, from 0.5 to 3.3 cc. per kilogram of weight, and the causes of death (cerebral or cardiac) in arterial embolism were studied according to the work of Allen, Hrdina and Clark. In the clinical study the author presents three case histories and stresses the etiologic importance of pneumectomy, pneumotomy, pneumothorax therapy and so on. In remarks about the symptomatology, he says that the nervous symptoms dominate the clinical picture. He mentions, among others, tonic and clonic contractions with exaggeration of the tendon reflexes, monoplegia or hemiplegia, generalized convulsions, coma, sensations of malaise, cold sweats, pallor and so on. Amaurosis, either unilateral or total, is the result of embolism of the retinal artery. The author observed this symptom in two of his three cases and regards it as especially important. In remarks about the treatment he stresses the reclining position as a preventive measure and says that acetylcholine is probably of therapeutic value, because of its vasodilatory effect.

 *Ovarian Dysfunction and Dermatoses: Therapeutic Action of Androgen in Certain Varieties of Psoriasis and Eczema. A. Lafitte and G. Huret.—p. 472.

Ovarian Dysfunction and Dermatoses.—Lafitte and Huret present the clinical history of five women from 16½ to 55 years of age whose diseases—some of long standing—successfully responded to treatment with testosterone acetate and after classic therapeutic measures failed to respond. The dermatoses reported were those of psoriasis and eczema and were found on the face, hands, lower limbs or universally. The treatments specifically mentioned varied from five injections of 10 mg. every other day to five monthly injections extending over three months and were applied between the twelfth and the twentieth day of the menstrual cycle. The method of administration, whether oral or otherwise, is not stated. In all these cases dermatitis was accompanied with great menstrual and mammary pain. The authors were able to effect permanent cures. They conclude that the results obtained with testosterone acetate clearly indicate that the seat of cutaneous diseases treated was ovarian imbalance and that, consequently, this therapy is effective only when cutaneous lesions are secondary to ovarian abnormalities. The best results were obtained, they say, in cases of especially severe menstruation and mastodynia. The authors are of the opinion that probably ovarian dysfunction may center in hyperfolliculism. Coexistence of psoriasis and eczema with ovarian disturbances on this background suggests the use of androgen. They think that other morbid manifestations such as urticaria, migraine, Quincke's edema, asthma and perhaps also hepatovesicular and intestinal disorders in women with the same pathologic indications might be benefited by this treatment.

 Surgical Treatment of Cancer of Left Flexure of Colon and of High Situated Cancer of Rectum with Conservation of Sphincter. H. Finsterer.—p. 488.

Pseudotumoral Encephalitis.—Roger and his associates point out that the term "pseudotumor" was first applied by Nonne in 1904 to those cases the clinical aspects of which simulated a cerebral tumor but in which the favorable development or the postmortem observations contradicted the diagnosis of tumor. Nonne's description included different meningeal, arachnoidal and parenchymatous lesions. In this report the authors present a diagnostic study of the inflammatory parenchymatous lesions. They first discuss the progressive forms of encephalitis, which, although more rare than the regressive forms, are better known. Among the forms of progressive encephalitis the leuko-encephalitides are the most important; they may appear in the form of Heubner-Schilder's disease and of Baló's disease. After describing the aspects of these two types, they report the clinical history of a case observed by themselves. The clinical aspects of this case are identical with those of a case of leuko-encephalitis of Baló described by Barré and Van Bogaert. The regressive forms of pseudotumoral encephalitis the authors classify into two groups. In the first group they combine the localized or circumscribed forms with a focal symptomatology, which are especially likely to simulate cerebral tumor. They describe the clinical histories of several cases of this type. The second group includes the more diffuse forms, in which the symptomatology varies greatly. The authors report the clinical histories of three cases of this type. Reviewing the clinical elements, which might be of value in the differentiation between neoplasm and encephalitis, the authors show that they are inconstant and of doubtful value. About the examination of the cerebrospinal fluid they say that the syndrome of intracranial hypertension with papillary stasis contraindicates lumbar puncture; the examination of the ventricular fluid, which they performed in the course of ventriculography, always showed normal results. Ophthalmoscopy reveals papillary edema; the diagnosis of pseudotumoral encephalitis can be based on this sign. The papillary edema is accompanied by considerable lowering of the visual acuity and abnormal modification of the visual field, but the most noteworthy ophthalmologic aspect is the absence of retinal arterial hypertension. Ventriculography gives the most reliable information for the detection of pseudotumoral encephalitis. Moreover,

it may even exert a favorable therapeutic influence. The prognosis of pseudotumoral encephalitis varies. Leuko-encephalitis has a fatal outcome but the regressive forms usually end favorably. The treatment consists in the early intense and prolonged administration of diffusible anti-infectious medicaments. Moreover, the endocranial insufflation of air may exert a powerful therapeutic effect. Craniotomy, besides being of exploratory value, is effective as a decompressive measure.

 Systematic Study of Arteriosclerosis of Spleen. G. Villará.—p. 529.
 Chronic Thrombosis of Pulmonary Artery. D. Ruffilli.—p. 546.
 Primary Cancer of Peritoneum: Case. G. Fragalà.—p. 595.

Arteriosclerosis of Pancreatic Vessels.—Villará studied the blood vessels of the head of the pancreas of fifty persons who had died over the age of 60. Arteriosclerosis had existed in forty-two of the cases. The author found arteriosclerosis in this site more frequent and more acute in women than in men. The pathologic changes of the vessels cannot be seen by the naked eye but are observable microscopically. The most frequent microscopic types are (1) hypertrophic thickness of the walls of the vessels, especially in the middle coat of the arterioles, minute vessels and precapillaries and (2) hypertrophy, hyperplasia and delamination of the internal elastic coat of the middle sized and large arteries. Hyaline and fat degeneration are frequent and thrombosis of the arteries may exist in some cases. There is a correspondence between the type and frequency of arteriosclerosis of the pancreatic vessels and those of the arteriosclerosis in the duodenal vessels, and between the former and the type and frequency of arteriosclerosis of other segments of the digestive tract, of the kidneys and of the thyroids. A relation between arteriosclerosis of the insular vessels and that of the parenchymal pancreatic vessels or between insular and parenchymal pancreatic arteriosclerosis and either hypertension or diabetes does not exist.

Visceral Rheumatism During Childhood.—Aschoff accepts the classification which Lötz suggested for the rheumatic diseases of childhood, differentiating the following forms: (1) acute specific articular rheumatism called also infectious rheumatism; (2) the nonspecific polyarthritides which may be produced by the distant action of various bacteria, especially diplococci, streptococci (coccic rheumatism of Gräff), tubercle bacilli or other types of bacteria and for which the existence of a so-called focus of infection is a prerequisite; (3) the so-called rheumatoids in scarlet fever, serum disease and so on; (4) primary chronic arthritis, especially Still's disease, and (5) muscular inflammations and myalgias, which, however, are comparatively rare during childhood. Aschoff shows further that several investigators agree that infectious rheumatism is the most frequent form of the rheumatic diseases occurring during childhood. He directs special attention to discussions by Klinge, Gräff and Ricker, pointing out that the last named author laid stress on Bouillaud's studies on the visceral forms of acute articular rheumatism. Aschoff agrees with Ricker in the acceptance of the term Bouillaud's disease but thinks that since it was Gräff who first demonstrated the primary focus of this disease, who detected the rheumatic nodules on the visceral organs other than the heart and who differentiated this form of infectious rheumatism from the other forms of rheumatic disorders, the disease should be designated as Bouillaud-Gräff's disease. Aschoff defends the specificity of the nodules that characterize Bouillaud-Gräff's disease. To Siegmund's assertion that scarlet fever likewise leads to the appearance of these nodules on the

heart, he replies that there is a possibility of a double infection. He also rejects Löwenstein's theory of the tuberculous origin, pointing out that the presence of tubercle bacilli in the blood does not necessarily prove the tuberculous etiology, for, since nearly every one contracts a tuberculous infection, it is possible that Bouillaud-Gräff's disease causes an irritation of the tuberculosis-infected lymph nodes at the pulmonary hilus which then throw their bacilli into the blood stream. In this connection he also directs attention to the frequent dissemination of a tuberculous process from a pulmonary focus in the course of whooping cough, stressing that in this event nobody maintains that the tubercle bacilli are the cause of the whooping cough. He insists that the nodules, in which no pathogenic organs have been detected hitherto, are characteristic for Bouillaud-Gräff's disease. At first they were detected only in the myocardium and the pericardium and its vessels but later they were detected also in the muscular tendons near the joints, in the dura mater in the first part of the aorta and in the vessels of the kidney and liver—that is, in the abdominal cavity. The author believes that Bouillaud-Gräff's disease, which is so frequently accompanied by articular pains, causes the formation of characteristic nodules not only in the heart and in the pericardium but also in the connective tissue in other parts of the organism. Nevertheless, he thinks that during childhood the visceral form of Bouillaud-Gräff's disease is restricted essentially to the heart and the pericardium including the coronary vessels, to the beginning parts of the aorta and the pulmonary artery, to the peritonsillar and cervical organs and to the dura mater and the tendons. To be sure, it is also generally admitted that besides the visceral form of Bouillaud-Gräff's disease there is also an articular form and that the periarticular nodules are noteworthy, especially during childhood.

Nature of Erythema Nodosum.—Kessler formulates his thesis as follows: erythema nodosum is an immunobiologic defense reaction of an organism that has been made allergic by an antigen; the antigen is formed by the tubercle bacillus or by a micro-organism that is biologically similar to it; the phenomenon develops when the causal agent is in the blood. In analyzing this thesis the author points out that Uffelmann suggested a relationship between erythema nodosum and tuberculosis even before Koch had discovered the tubercle bacillus. Later, the close relationship between tuberculosis and erythema nodosum was demonstrated by means of the tuberculin reaction. However, some investigators raised objections, pointing out that there are cases of erythema nodosum that react negatively to tuberculin. Following a discussion of the symptomatology of erythema nodosum, the author reviews the literature on the problem of its relationship to tuberculosis, giving special attention to Ernberg's studies, which subsequently were corroborated by other investigators. Then he describes his own observations on erythema nodosum. In the course of an epidemic of measles, he observed it in eight children who for several months had consumed milk from tuberculous cows. In connection with these cases he inquires whether the appearance of the erythema nodosum concurred with the first increase in the allergy following the tuberculous infection or whether the nodular eruption represents merely a fluctuation in the allergy of a tuberculous patient, the fluctuation having been caused by the measles. He cites factors that indicate the first possibility; for instance, a tuberculous meningitis was produced in a nursing by the same infected milk, the consumption of which in the other children was followed by the appearance of the erythema nodosum. In the summary the author stresses that erythema nodosum is an allergic phenomenon which develops in patients with tuberculosis, when simultaneously with great fluctuations in allergy, especially during the first increase, there exists a bacillemia. This allergic phenomenon is a biologic process which is not restricted to tuberculosis but which is nevertheless chiefly observed in patients with tuberculosis. In the Scandinavian countries tuberculosis is the causal factor of erythema nodosum in 95 per cent of the cases; in England and America in approximately 70 per cent. Erythema nodosum has been observed after scarlet fever in patients in whom tuberculosis was definitely absent. In scarlatina the erythema develops likewise at the time of a decided change in allergy, that is, from three to four weeks after the scarlet fever exanthem. Streptococci seem to be the causal organisms in such

cases. In this connection the author points out that some investigators who do not accept the tuberculous etiology of erythema nodosum regard streptococcal infections at least as a second etiologic possibility and interpret erythema nodosum as a nonspecific allergic syndrome. In the concluding paragraph the author points out that American authors called his attention to the frequent occurrence of erythema nodosum in cases of coccidioidal granuloma, a disorder which resembles tuberculosis in many respects, but in which the tuberculin reaction is negative.

*Operative Indications in Acute Pancreatic Necrosis. V. Schmieden.—p. 274.
Gallstone Ileus, Its Roentgen Diagnosis. G. Petré.—p. 278.

Pancreatic Necrosis.—The severe types of acute pancreatic necrosis are rare, according to Schmieden, while mild forms, frequently masked by gallstone disease, are rather common. The etiology of the disease is quite complicated, involving a number of pathologic as well as physiologic-functional factors. A stone in the papilla and the infected cholelithiasis do not explain all of the process. Surgical intervention is indicated in cases in which the diagnosis is not certain, as well as in the severest forms of pancreatic necrosis. The circulatory collapse in such cases is probably due to the entrance into the circulation of the liberated trypsin and consequent dilatation of the vessels, while the products of digestion contribute to shock and the death of the patient. The intervention should be limited to drainage of the pancreatic area and in some cases of the biliary tract as well. The pancreas must not be incised or torn with the finger, as was the practice in the past. One should not operate in the presence of a severe circulatory collapse, uremic manifestations or beginning diabetic coma. The conservative medical treatment of severe cases is permissible only when no doubt as to the diagnosis exists.

Lymph Node Metastases of the Neck.—Schürch and Fehr discuss the operative treatment of chronic lymph node metastases developing in the course of a malignant process in the mouth or the pharynx. Their conclusions are based on an analysis of 113 cases in which the operation for the removal of the lymph nodes was performed at Clairmont's clinic, Zurich, between the years 1927 and 1936. Palpably enlarged lymph nodes in 25.7 per cent of the cases suggesting malignant degeneration proved, on microscopic examination, not to be malignant, while in 67.3 per cent of the cases the clinical diagnosis of malignancy was confirmed by the microscopic examination. The operative mortality was 11.4 per cent. The five year survival of patients with carcinoma of the lips amounted to 61.5 per cent. The percentage of five year survival was 50 in cases of lymph node metastases microscopically demonstrated and 80 in cases in which there was no lymph node invasion. The five year survival in cases of carcinoma of the oral cavity amounted to only 14.9 per cent, with three year survival in 17.5 per cent. Cases of lymph node involvement yielded 8.8 per cent of five year survival, while in those in which there was no lymph node invasion it was 33½ per cent. Of the forty-two patients with carcinoma of the tongue, 14.3 per cent survived five years, those with neck metastases yielding 5 per cent and those without, 42.9 per cent of survivals. The authors conclude that in order to be effective the operation must include the removal in a block of the submental, submaxillary and the deep nodes with resection of the external and internal jugular veins and the sternocleidomastoid muscle. This operation gives better results than irradiation alone. The operation is applicable only in cases

in which the malignant cells have not invaded the capsule of the lymph node or the surrounding connective tissue. Operative intervention in the latter type is likely to be followed by a rapid and diffuse invasion of the loose connective tissue by the malignant cells. In cases in which the possibility of the removal of the nodes *en bloc* appears doubtful, preparatory irradiation should be applied. In a few cases irradiation makes operation possible. Here, however, the prognosis is unfavorable. The authors consider it necessary to remove the nodes on both sides when the tumor reaches the midline or reaches beyond it.

Gastric Secretion and Basal Metabolism in Chronic Arthritides.—Edström says that, since Woodwark and Mackenzie demonstrated in 1912 that chronic articular rheumatism is often associated with achylia, considerable attention has been given to the secretory conditions of the stomach in this disorder. Edström himself describes studies on the gastric function of several hundred patients with rheumatic disorders who have been admitted to the university hospital in Lund, Sweden, since the beginning of 1936. The gastric function was examined by means of fractionated test breakfasts. In cases in which no free hydrochloric acid was obtained during the first hour after the introduction of the tube, 0.5 mg. of histamine was administered by subcutaneous injection. Of 432 patients with typical chronic rheumatic infectious arthritis, eighty (18.5 per cent) had an achylia that proved refractory to histamine provocation and in an additional forty-nine (11.4 per cent) subacidity was detected. Thus the gastric secretion was reduced in about 30 per cent of the cases. The achylia proved to be more frequent among the severe cases than among the milder cases, but the duration seemed to have no influence on the presence of achylia. The frequency of the achylia seemed to increase with advancing age but in all age groups the incidence of achylia was higher in the patients with arthritis than in the control material (without arthritis). On the other hand, there was no evidence of a relationship between secondary anemia and achylia. In 148 cases of rheumatic fever with chronic arthritis the examination of the gastric function by means of the test breakfast disclosed no divergence from the normal. In fifty of the aforementioned 432 cases of chronic rheumatoid arthritis the fractionated test breakfast was repeated at long intervals. Many of the patients had improved in the meantime. Of twenty-three cases of achylia refractory to histamine on the first occasion there remained only twelve on the later occasion. Of eight subacid cases at the first examination, five showed normal secretion at the second. Only two of the cases that showed subacid or normal acid conditions at the first examination showed achylia refractory to histamine at the second; both presented a clinical deterioration. In 369 of the aforementioned 432 patients with chronic rheumatic infectious arthritis, the basal metabolic rate was studied. Placing the limits for the normal at plus or minus 10 per cent, it was found that 24 per cent showed subnormal, 70 per cent normal, and 6 per cent supernormal values; that is to say, the basal metabolic rate was on the average below the normal. Those patients who had concurrent achylia showed a lower mean basal metabolic rate than the others; moreover, the severe cases showed a predilection for subnormal values of the basal metabolism. The basal metabolism was examined also in 120 of the 148 cases of rheumatic fever with chronic arthritis. The values were found to be normal in 67.5 per cent, subnormal in 17.5 per cent and supernormal in 15 per cent of the cases; that is, the average was normal. Subsequent basal metabolic tests disclosed that, of seventeen who had had subnormal values at the first test, thirteen had now normal rates. Many of those

who showed an increase in the metabolic rate also showed clinical improvement. On the other hand, of five in whom previous normal rates had decreased to subnormal ones, three showed clinical deterioration. The author concludes that the lowered basal metabolic rate and the reduced secretory activity of the stomach are secondary to the rheumatic lesion; they are merely clinical symptoms of the general impairment of the mesenchyma that is present in chronic rheumatic infective arthritis.

Pellagra in Uniovular Twins.—Mainzer reports the clinical histories of two young women who were uniovular twins. Both of them had the same type of pellagra, although they had lived in different continents for three years previous to the development of the disease. Moreover, none of the persons who ate with them at the same table showed symptoms. The disorder as well as four relapses and remissions developed simultaneously in the two sisters. The nutrition had been adequate; the diet included moderate amounts of corn. The author thinks that these two cases demonstrate the presence of an endogenic factor in pellagra with the conclusiveness of an experiment. That the disorder actually was pellagra cannot be doubted. It became manifest in the twin sisters with completely identical cutaneous manifestations with psychic symptoms and with hyperchromic anemia. Digestive disturbances were present in only one of them. A glossitis was demonstrable in neither of the sisters, but the papillae of the mucosa were atrophic. That the two sisters are uniovular twins is proved not only by their great similarity in appearance but also by the similarity in pathologic and physiologic functions. The basal metabolic rate was slightly reduced in both of the sisters and both were subject to menstrual disturbances. Both had severe degrees of myopia. A number of functional disturbances showed a considerable degree of similarity in the two sisters: The electrocardiograms were identical. The fasting blood sugar values (low but normal) were practically the same and after the administration of insulin the values were again practically identical. The nitrogen rest, uric acid, chloride and cholesterol contents of the serum were identical within the margin of error. The diuresis of water and chlorides and the total molecular excretion on the hydrogen ion diuresis in tolerance tests showed great similarities. Other functions, however, were dissimilar. The author concludes that the reported observations demonstrate the importance of endogenic factors in the pathogenesis of pellagra.

Blue Scleras.—Jensen and Ortmann, reporting two cases of Lobstein-Eddow's disease, osteopsathyrosis idiopathica, say that in the disorder blue scleras, a tendency to fractures and otosclerosis constitute a triad. As seen in their second case, blue scleras are not always accompanied by the tendency to fractures. There is generally a proportionality between the degree of coloring and this tendency. All authors agree that blue scleras are the dominating symptom. The color has been observed in five generations and established in fifty descendants of one person. A certain intensity of the coloring, familial character, and combination in at least one member of the family with osseous and auditive stigmas are necessary for positive diagnosis. The abnormal fragility of the bones depends on insufficient periosteal ossification coincidentally with inability of the bone tissue to take up calcium. The patients may become greatly deformed; in extreme cases there are "glass men." The deeper cause of the symptom complex is unknown. While in one family the disorder has appeared only in twenty male members, as a rule both men and women are affected. Transmission is probably dominant. The disorder may skip several generations, to reappear as the result of exogenic factors (disease) or endogenic factors (puberty, gravidity).

COLLAPSE THERAPY AT CHICAGO MUNICIPAL TUBERCULOSIS SANITARIUM

A CRITICAL STUDY OF 8,083 CASES

FREDERICK TICE, M.D.

AND

ALLAN J. HRUBY, M.D.

President and Secretary, Respectively, Board of Directors, City of
Chicago Municipal Tuberculosis Sanitarium

CHICAGO

In the May 7, 1938, issue of *THE JOURNAL*, under Current Comment,¹ with reference to an article on fatality trends by G. D. Drolet, the commentator expressed surprise at Drolet's conclusion that the surgical treatment of pulmonary tuberculosis had little effect on the case fatality rates of the tuberculous population. "This constitutes a surprising statistical conclusion in view of the apparent individual effectiveness of such measures as pneumothorax. Further analytic studies should be made before it can be safe to conclude that therapeutic measures in pulmonary tuberculosis are as ineffective as they appear to be statistically." We are in complete agreement with this sentiment and wholeheartedly endorse the necessity for further analytic studies on collapse.

Such a study is offered in this paper, a study of all the patients treated with collapse who were registered at the City of Chicago Municipal Tuberculosis Sanitarium from Jan. 1, 1931, to July 1, 1936, and observed to July 1, 1937. In all, 8,083 patients were examined: 3,090 treated more than three months, 337 treated less than three months, 330 for whom pneumothorax was attempted, 742 whose records were thrown out as not sufficiently complete for compilation and 3,584 controls, a group made up of persons dismissed from the Sanitarium as a routine, persons who refused pneumothorax or for whom it was attempted, patients with adhesions and patients obviously so noncooperative that collapse was contraindicated. The treated patients were all subjected to some measure of collapse, either at the Sanitarium proper or at the field collapse clinic, and the number includes all who received treatment at both the clinic and the Sanitarium under the plan of conjoined extramural and intramural collapse as practiced over the period in question.

A word as to this conjoined plan. The Sanitarium and the dispensaries, unified as to function and objective through one board of directors, cooperate toward a general collapse program. The organization as a whole still adheres to the principles originally formulated in

1931, collapse for all suitable patients inside the Sanitarium (68.8 per cent of the total population at the present time), collapse for all reachable patients outside the Sanitarium from the initial injection onward (1,428 patients under observation and treatment), dismissal of Sanitarium patients as soon as possible, admission to the Sanitarium of such field patients as fail to respond or in whom complications develop, and supervision in the home facilitated by a staff of 142 field nurses who visit patients after their injections and make frequent calls to insure compliance with the pneumothorax schedule.

The accompanying chart indicates the locale of treatment for the 2,824 patients subjected to collapse in the six and one-half year period.

As will be seen, 39.8 per cent of the patients were treated exclusively at the Sanitarium and 23.4 per cent exclusively at the clinic, 7.4 per cent started at the Sanitarium and finished at the clinic, 8.8 per cent started at the clinic and finished at the Sanitarium, 9 per cent started elsewhere and continued at the clinic or Sanitarium, 4.2 per cent started at the clinic and finished at the Municipal Home for the Open Case,² 3 per cent started at the clinic and finished at other institutions, and 4.4 per cent started at the Sanitarium and finished at other institutions.

The technic of the survey included recent x-ray examination and reexamination of all patients under treatment and the same or the equivalent for all dismissed patients brought within reach by the following measures: nurse's visit to the home to bring in the patient for reexamination, nurse's investigation of the neighborhood to locate lost patients, similar investigations in other dispensary districts for patients who have moved, gas company and postoffice inquiries, letters, sent first class to the last known address, and letters and questionnaires to private physicians, to patients out of town and to other institutions. Of the treated patients, 89.3 per cent of the Sanitarium patients were traced and fully studied, as against 93.7 per cent of the clinic patients and 92.5 per cent of those who received treatment at both the clinic and the Sanitarium. In view of the circumstances and the volume, these figures, a total of 8.6 per cent lost of 3,090 patients, are considered satisfactory.

In American cities, tuberculous patients of the type cared for by the City of Chicago Municipal Tuberculosis Sanitarium are notoriously hard to keep track of. The overwhelming majority are in the lowest socioeconomic brackets and present the usual difficulties incident to those levels. Despite the most thorough follow-up they discontinue treatment, move, hide and

leave town, seeking, with the restlessness of their type, the panacea of Arizona or even more deceptive will-o'-the-wisps. The migratory worker with his lung collapsed feels confident that he is cured and follows the harvest. The railroad laborer, similarly situated and motivated, goes back to his gang. At the first snowfall

Distribution of patients treated.

equation. In a disease as protean and unpredictable as pulmonary tuberculosis, it is impossible now, and always will be, to set off against each other any two groups of cases with identical or even similar diagnostic facets and prognostic ideologies. No two cases are alike. Even if they were alike today, one has no assurance that some weeks or months hence they will not be as far apart as cavity and cicatrix. Even within the limits of one organization the control is a hurdle, a stumbling block in the path of exact comparative analysis.

The problem becomes still more acute, the stumbling block more discouraging, when one goes outside one's own institution and attempts to mold one's measuring rod from a conglomerate of unfamiliar and dissimilar material drawn from different sources, as represented by questionnaire studies from various institutions, compilations from the literature and the establishment of criteria on the basis of presumptive morbidity against the official mortality tables. The latter procedure, recently practiced both here and abroad, to the detriment of a true understanding of the results of collapse, is especially deceptive. Morbidity is an unknown quantity, the case report a creature of its environment and the figures presumptive. In attempting to balance the tuberculosis mortality of today against the morbidity of ten or twenty years ago, one encounters a host of variables, intangibles and imponderables—the report as influenced by propaganda, campaign activities, public health leadership, legislation and the enthusiasm of a new organization, the special surveys incident to the establishment of a sanatorium, and the changing diagnostic attitudes that every one knows have been a feature of the tuberculosis picture during the last two decades. The true incidence of tuberculosis is one thing and the reported incidence another, and both phases of the question are subject to modifying influences that destroy the value of morbidity as a base.

An estimation of the results of collapse based on sanatorium mortality ratios in the precollapse era as compared with those current at this time stands on an equally precarious footing. The measuring rod possesses some of the flaws already mentioned and has a few more individual to itself, i. e. the competition for beds, the lessened incidence of tuberculosis with more

the patient of the hobo type believes that he will do better in a sunnier clime and hops a boxcar for the south.

We do not mean to intimate that the Arizona-bound hobo and the railroad laborer constitute the bulk of our patients. Actually they form but a comparatively small margin. The margin, however, is appreciable and objectivates itself in a minimum number of patients who absolutely cannot be traced by any technic short of some system of national registration and passport.

In the control group, including a large percentage of patients with minimal involvement (562, or 16 per cent), for reasons already given and other reasons to be discussed, the proportion of untraced patients rose considerably higher, an average of 15.9 per cent. A large fraction of the patients lost were patients with incipient tuberculosis, a type difficult to control or supervise. Minimal tuberculosis in an institution with 1,467 beds and a dispensary roll of 20,000 patients with tuberculosis is a fluctuant quantity. Notwithstanding a well trained and conscientious staff, "busy day diagnoses" creep on the records: nontuberculous conditions, hyperthyroidism, anemia, heart disease, bronchitis, silicosis, sinusitis, bronchiectasis, innocuous tuberculous conditions, hazy apexes and suspected tuberculosis. These patients, in other words, are the chaff of the clinic, who need little treatment, collapse or otherwise, and react to indifference by disappearance.

The force of this reaction became very evident as the investigation progressed. The patient who received treatment could be kept under supervision; the longer the treatment, the closer the tie. The patient with minimal or nontuberculous involvement in need of no special care drifted off and came, as indicated, to form a considerable proportion of the lost controls.

As far as collapse is concerned, it is necessary to say here and now that the control at best forms a doubtful

* Including permanent collapse procedures as well as pneumothorax.

actual and relative sanatorium accommodations now than formerly, permitting entrance of a greater number of patients in advanced stages, the recent trend of patients with advanced tuberculosis toward the sanatorium for collapse, and changing policies, as determined by the personality of the officers and changing administrations affect the admissions. The admissions regulate the deaths; the number who die will depend on the composition of the material at the gate.

In the present investigation, in addition to the patients for whom pneumothorax was attempted and patients not subjected to collapse, another control was used.

The final and perhaps the most satisfactory assay of the results of collapse was made against the life expectancy of patients with open tuberculosis as authenticated by the records of the Sanitarium and dozens of reports of unanimous context in the literature.

The rationale seemed good. Open tuberculosis holds the substance of this entire report. The material for treatment was bad, 94.2 per cent with advanced tuberculosis, 84.4 per cent with positive sputum and 81.3 per cent with cavity formation. Included in the survey were 439 Negroes (14.2 per cent), who must be considered against their relevancies, the existent tuberculosis mortality in Chicago, a ratio of 6 to 1 in comparison with that for the white race.

With this picture as an index of expectancy, what were the actual results? Table 1 gives the first split. The table shows that 69.3 per cent of the 3,090 patients treated more than three months were living at the date of the report. Of the remaining 4,251 (treated less than three months, pneumothorax attempted, no col-

sions for "no collapse" patients with the 1,215 conversions for patients treated more than three months. A comparison with the previous table and a simple calculation will make the situation clearer still. If we had not eliminated the dead but had based the conversions on total patients, we would have had a conversion ratio of 51 per cent for the treated patients as against 13.8 per cent for the controls.

Table 4 has to do with the stage of disease as crossed against end results. The 6,403 completely traced patients were studied. The term initial diagnosis as used in the table signifies for the treated patients diagnosis at the time collapse was started and for the controls diagnosis on registration in the dispensaries or admission to the Sanitarium.

In the group with minimal tuberculosis, the difference of 3.6 per cent between the treated and the untreated patients is interesting. The much larger number of patients with minimal tuberculosis in the control group must be taken into account, as must the "busy day

lapse) 1,427, or 33.6 per cent, were living, which indicates a survival ratio of better than 2 to 1 in favor of the treated patients.

Table 2 epitomizes the end results with 2,824 treated patients as against 3,579 controls, a total of 6,403 traced patients. The table is self explanatory and portrays a sharp differential in the better clinical classifications as between treated patients and controls. The number dead of the patients treated more than three months is considerably less than half that in the other groups.

The City of Chicago Municipal Tuberculosis Sanitarium since its inception has been oriented toward public health aspects of tuberculosis. Open tuberculosis is now and always has been strictly regulated, and isolation of the carrier from children is mandatory. With this background, needless to say the conversion of sputum comes in for considerable attention.

Table 3 deals with the living patients from the standpoint of the conversion of sputum. This table, though it shows a differential of over 16.2 per cent in favor of the treated patients as against the "no collapse" patients, does not tell the story. Only the living patients were studied, and the much higher mortality for the "no collapse" patients (60.7 per cent, against 24.1 per cent) distorts the end results. The smaller the number of survivors, the less significant the ratio. A more correct impression is received by comparing the 337 conver-

diagnoses" already referred to. In an institution that sincerely advocates collapse for early tuberculosis, the percentage of patients with minimal tuberculosis among the controls is significant. Undoubtedly many of these patients, whose condition was hastily diagnosed in the rush of a dispensary, were dismissed when they came to conference for collapse. The groups "treated less than three months" and "pneumothorax attempted," nine and thirteen patients respectively, are too small to receive undue attention. The real meaning of the table is seen in the groups with moderately and far advanced tuberculosis, with 83.3 as against 57.7 per cent living in the former and 70.5 as against 21.5 per cent living in the latter.

The tables adapting the national classification to the stage of the disease are too lengthy to be included in a paper of this scope. Roughly, the results parallel the mortality as indicated in table 4. In the group with far advanced tuberculosis, for instance, 60.4 per cent of the treated patients fell in the better classifications (apparently cured, arrested, apparently arrested, quiescent, improved), as against 14 per cent for the controls.

Regarding conversions among the living patients, 84.8 per cent of those with minimal, 80.4 per cent of those with moderately advanced and 72.4 per cent of those with far advanced tuberculosis lost their bacilli permanently.

So far the figures lack something, something of first importance, the element of time as crossed against results. What is the answer to the crucial inquiry "How long?" How many of our 2,824 traced patients were alive after one, two, three, four, five or six years? Table 5 furnishes the details on this.

* Including permanent collapse procedures as well as pneumothorax.

Summarizing the highlights of the histories of the 171 patients subjected to collapse prior to 1931 and treated more than three months, 110, or 64.3 per cent, are living. Of the 421 "no collapse" patients, 132, or 31.3 per cent, are living. In other words, the patients treated with collapse did twice as well as the untreated patients. This ratio in favor of treated against untreated patients is steadily maintained for the succeeding years, from 1931 to 1936. Comparing the controls and looking at the tabulation all the way through, one sees that approximately twice as many treated patients as controls are living.

It may be alleged, and with some justice in view of ideas already enunciated, that the controls are not valent, that the groups are not similar and that the study failed, as all large studies on collapse must, in establishing anything approaching identity of symptoms, comparability of the pathologic process and prognosis. All right! Let us try another tack! Let us forget the controls established in the investigation and check the results against the published and repeatedly authenticated figures on the prognosis of open tuberculosis, the type of tuberculosis dealt with in this report, 94.2 per cent advanced and 84.4 per cent with positive sputum. How does tuberculosis of this kind turn out? Against the unfavorable hygienic and economic backgrounds, what is the outlook for the bacillifer? What is his life expectancy? Bad! If the consensus among dispensary and institutional officers is worth anything, very bad!

With from 75 to 90 per cent of patients of the type seen at municipal institutions in metropolitan centers,

positive sputum is a death warrant within five years. No mere impression this! A special study, made as of Dec. 31, 1931, of all patients with open tuberculosis registered with the City of Chicago Municipal Tuberculosis Sanitarium previous to the year 1927 emphasized the fiber and the irrevocability of the death warrant. Of the 8,779 patients studied, 82.96 per cent were dead at the end of five years and 91.16 per cent at the end of ten years. There is nothing new in this.

One does not have to plunge very deep in the literature to find ample confirmation for the figures of the Sanitarium. William Farr, working with Louis and Bayle's records, found the law of mortality for phthisis (hospital patients) as follows: 62 per cent were dead the first, 85 per cent the second and 95 per cent the fifth year after the manifestation of symptoms. In 1909, of 108 patients with pulmonary tuberculosis, Prindle found 50 per cent dead the first year and 80 per cent dead within three years. In Jena, for patients who came under observation in 1920 and 1921, Kayser-Petersen found a mortality of 68.2 per cent after five years; in Stetten in a similar study, Braeuning found a mortality of 79 per cent. Lissant Cox found that of 736 patients with open tuberculosis studied after 1920, 90.2 per cent were dead after thirteen and one-half years and of 802 studied after 1925, 88.5 per cent were

dead after eight and one-half years. The English County Council reports tell a similar story, 64 per cent dead after four years, 68 per cent dead after five years and 72 per cent dead after seven years.

The London County Council reports, involving the turnover of approximately 4,000 patients a year for the years 1921 to 1929 inclusive, carry the same theme,

an average survival rate after five years of 32 per cent for the patients with moderately advanced tuberculosis and positive sputum and 5 per cent for the patients with far advanced tuberculosis. Such is the prognosis of open tuberculosis, a prognosis that the joint collapse program sought to modify in a favorable direction. The effort met with an appreciable measure of success.

TABLE 6.—Unilateral Versus Bilateral Treatment Crossed Against End Results (2,824 Patients)

Total.....	2,824	44	1.5	429	15.2	420	14.9	392	13.9	586	20.8	271	9.6	682	24.1

in 1931, 66.5 for 1932, 70.2 for 1933, 76.4 for 1934 and 83 for 1935. Irrespective of the status of our "no collapse" patients, these figures stand out and are buttressed by the grand control, the uniform observation and results of all who have had experience with open tuberculosis.

What influence if any could be attributed to the extent of intervention as represented by unilateral and bilateral treatment? Of the 2,824 patients subjected to collapse, 2,259, or 80 per cent, were treated unilaterally and 565, or 20 per cent, bilaterally. The study, while perhaps of academic interest only, nevertheless is included (table 6). From the table it will be seen that 579, or 25.7 per cent, of the 2,259 patients treated unilaterally were dead at the time of the report, as against 103, or 18.2 per cent, of the 565 patients bilaterally treated. The composition of the groups with apparently cured, arrested and apparently arrested tuberculosis, however, is in favor of the patients subjected to unilateral treatment. In other words, there seems to be a conflicting theme in this compilation, a relatively larger number of survivors in the bilaterally treated group, with a diminished ratio of improvement for the group in general. While conflicting on the surface, this inversion of the ratios fits in well with the pathology of bilateral tuberculosis and the indications as materialized in bilateral treatment.

The table on conversion for this study, which it was not thought necessary to include, follows the pattern, 77.7 per cent of conversion for unilateral treatment as against 68.5 per cent for bilateral treatment.

FIELD COLLAPSE VERSUS SANITARIUM COLLAPSE

Is large scale field collapse successful? From the point of view of end results and conversion, how does it compare with collapse established and maintained in the Sanitarium? The answer to this question constituted one of the main objectives of the investigation. After a six and one-half year trial we were anxious to determine how the patient subjected to extramural collapse fared and how the field stood up in relation to the ideal locale for collapse, the sanatorium. Table 7 gives the breakdown.

First, loosely summarizing, the table shows 30 per cent of the clinic patients with tuberculosis apparently cured, arrested and apparently arrested, 27.2 per cent with the disease quiescent and improved, 9.3 per cent with it unimproved and 33.5 per cent dead, as against 26.2 per cent in the best categories for the Sanitarium, 40 per cent with the disease quiescent and improved, 9.7 per cent with it unimproved and 24.1 per cent dead. The discrepancy in the percentages of patients with apparently cured, arrested and apparently arrested tuberculosis (30 per cent against 26.2 per cent) in favor of the clinic is in all probability a superficiality. On the whole the extramural clinic did not do quite as well. When all the better classifications are combined, the clinic shows 57.2 per cent of the patients with the dis-

ease apparently cured, arrested, apparently arrested, quiescent and improved, as against 66.2 per cent for the Sanitarium and 75.1 per cent for clinic and Sanitarium combined. The mortality ratio emphasizes this trend still more: 33.5 per cent dead for the clinic, 24.1 per cent dead for the Sanitarium and 15.1 per cent dead for the group receiving both clinic and Sanitarium treatment.

The figures seem logical. Sanitarium results normally should be superior to the results of field collapse,

TABLE 8.—Initial Treatment Against Place of Application (3,090 Patients)

Initial Treatment	Total		Living		Dead		Untraced		Patients Known to be Living

and the combination of Sanitarium and clinic treatment, with the implied follow-up in the home, should show up best.

When the extramural program was being considered, it was well realized that ideally pneumothorax should be induced at the Sanitarium. This ideal, however, was impossible of attainment. In view of the accommodation shortage, even a relatively brief period of preliminary stay was out of the question. With some misgivings and for lack of other solution, the directors

had to envisage the initial injection in wide application outside the Sanitarium. The scale turned in favor of widespread extramural collapse from the initial injection onward, and in the six and one-half year period there has been no cause to regret the decision. Table 8 gives the results from the standpoint of the initial treatment. Viewing all cases from this standpoint irrespective of other considerations, it will be seen that 70.6 per cent of the patients who started treatment

TABLE 9.—Type of Treatment Against Results (3,090 Patients Treated More than Three Months)

at the clinic were living, as against 78.1 per cent of those who started at the Sanitarium. The figures are sufficiently large and sufficiently close to establish a just comparison. The difference of 7.5 per cent in the results speaks well for the thesis that pneumothorax can be safely and competently induced in the field.

With reference to the 398 patients who started treatment elsewhere, these were ambulant patients from other institutions with a pneumothorax already well established when first seen.

From the first the conjoined clinic and Sanitarium plan has stressed collapse as a sequential treatment regulated to the individual patient for the individual indication. The institution is prepared to give every patient, inside the Sanitarium or outside, the benefit of all the ancillary measures as well as of pneumothorax. With the exception of thoracoplasty and one or two other measures, the clinic is equipped to give all collapse procedures. Patients needing thoracoplasty or the other special measures are referred to the Sanitarium. In the course of the investigation a study was undertaken to define the results of the various operations and combinations. Table 9 represents this study. It will be seen that "phrenic operation only" showed the poorest results, 65.9 per cent, as against 75.8 for "thoracoplasty only," 76.7 for "pneumothorax only," 73.4 for "pneumothorax and pneumonolysis," 78 for "pneumothorax and phrenic operation," 79.2 for "pneumothorax and oil" and 82.4 for "thoracoplasty and other collapse."

In addition to the results of thoracoplasty quoted here, Davison, our consultant in thoracic surgery, made a special study of 393 patients operated on at the Sanitarium and observed in the period from 1927 to 1938. Sixty-nine per cent were living from seven to eleven years after operation, 79 per cent from five to seven years after operation, 83 per cent five years after operation, 79 per cent four years after operation and 90 per cent three years after operation.

How were the results of pneumothorax proper influenced by the percentage of collapse? Balancing the total end figures against the degree of collapse, the tables (not sufficiently important to be introduced in a paper of this length) followed the accepted formula

that, other things being equal, the greater the degree of collapse the better the results; 39.2 per cent of the patients with an average collapse of 30.0 per cent were dead at the time of the report, 32.9 per cent of those with a 30.0 to 60.0 per cent collapse were dead and 21.9 per cent of those with a collapse of 60.0 per cent and over were dead.

In the Chicago collapse plan, from the first, special attention has been devoted necessarily to the Negro. Tuberculosis in this race constitutes a large part of the local problem. In 1937 an estimated Negro population of 250,000, 7 per cent of the total population, accounted for 35 per cent of the deaths from tuberculosis. In view of these figures and of the socio-economic and health factors, every effort was made to get members of the race under treatment. In all, during the six and one-half year period, 1,071 Negroes were observed, of whom 439 were actually submitted to some form of collapse. The results, balanced against those for the white race, are shown in table 10.

At first the results of collapse in the Negro may seem unfavorable; 57.4 per cent of the Negroes were living as against 78.9 per cent of the white patients, a gap of 21.5 per cent. In judging the issue, however, one must bear in mind that in Chicago the recorded mortality ratio as between Negroes and white persons is 6 to 1. The figure in our study, 57.4 against 78.9, representing a Negro to white person ratio of 1 to 1½, is considerably better. This difference, even if further studies prove it constant, is well worth working for. It is quite possible too that another series of patients might show better response. The possibility is suggested by the fact that response in Negro women was much better than in Negro men, 65.8 per cent living as against 49.6 per cent. Much more research is necessary on this point. Notwithstanding the fact that from every angle collapse in the Negro is of first importance, it has had to date amazingly little attention.

Chadwick, Markoe and Thomas³ reported the cases of 464 Negroes treated in Detroit sanatoriums, 67.0 per cent with far advanced and 23.0 per cent with moderately advanced tuberculosis, of whom 70.0 per cent

TABLE 10.—End Results Against Race and Sex (6,271 White Persons and 1,071 Negroes, a Total of 7,341)

received collapse therapy. Of the discharged patients, 28.0 per cent had the disease arrested, and of the patients still under treatment at the time 53.0 per cent were showing a favorable response. Unfortunately the figures are not complete; the conversions are not given, the length of treatment was not studied and data are not available as to condition after discharge.

These authors also studied the relative response in Negroes of pure and of mixed blood. This too is a subject that needs further research. It is no mere academic question. Granted race as an element in susceptibility, it is only natural to suppose that the

3. Chadwick, H. D.; Markoe, R. C. L., and Thomas, J. T.: Collapse Therapy of Pulmonary Tuberculosis in Negroes, *Am. Rev. Tuberc.* 28: 759 (Dec.) 1933.

factor would operate more obviously in full-blooded Negroes than in mulattoes. In Chadwick, Markoe and Thomas's study the tenet was borne out as it applied to the light Negro. "The very dark Negro, on the other hand, had a higher percentage in the favorable group than did the medium colored patients." They conclude that "the degree of color, other than the very light, is not an index of response to tuberculosis."

Nash,⁴ from the clinic of the Atlanta Tuberculosis Association, reported on forty-eight patients treated from June 1933 to June 1936. The average length of treatment was nine months. Thirty-five per cent had a successful collapse and 54.0 per cent an unsuccessful one. Fifteen, or 88.0 per cent, of those with successful collapse were classed as having the tuberculosis improved, apparently arrested or arrested.

It is surprising that the inherent possibilities of collapse for the Negro have been so little studied. Since in the United States, of a population of 12 million Negroes about 250,000 need hospitalization for tuberculosis, with only about 7,500 beds, or about 3.0 per cent, to receive them, extramural collapse would seem to offer at least a large fraction of the solution. There are of course, difficulties that will not be cured by collapse, such as economic and hygienic factors, housing (several families to a flat, several adults and children to a room, exposure to active tuberculosis of both children and adults who have a negative reaction to tuberculin) lack of medical and nursing care among the Negroes and, last though not least, the much discussed and intricate issue of resistance. How much weight the last factor carries in the lessened response to collapse (if lessened response there is) cannot be said. Though environmental, adaptive and economic factors must be given some influence, there is undoubtedly something else, a racial element modifying resistance, an innate tendency to a more foudroyant type of disease in the Negro. To quote Long:⁵ "The tuberculosis in the Negro, as compared with the average in the white, is generally more massive in character with more tendency to caseous pneumonia and to generalization by both blood and lymph streams, with resultant wider variations in anatomical type." Or Pinner and Kasper:⁶ "We are impressed by the necessity of considering the likelihood of true genotypic differences between the two races in order to explain their different reactions to tuberculosis."

Irrespective of the underlying causes, the fact remains that the Negro carries a large proportion of the open tuberculosis in cities like Chicago. In a collapse program he should receive a share of attention, graduated generously in accordance with the urgency of his problem.

In a paper of this type it is impossible to cover in detail the story of the complications as revealed in the investigation. We restrict ourselves to one, air embolism. Table 11 shows the incidence of this complication from 1931 to 1937 inclusive.

In all there were 83,245 treatments, with one embolus to every 2,973 injections. The gradually decreasing rate of accident from 1931, when the work started, to the present is meaningful. The last embolus occurred

on May 25, 1937. Since that date, through a total of 21,000 treatments, no accident of this kind has occurred.

The fact needs to be stressed that this is field collapse and advanced tuberculosis. Of the twenty-seven patients eight died, one twenty-five minutes, one four hours, one thirty-five hours, one thirty-six hours, one four days and three ten days or more after the injection.

The figures, twenty-eight to 83,245 treatments, compare favorably with reports in the literature for institutionalized collapse and dispose of the contention that extramural collapse, from the initial injection onward, is necessarily a hazardous undertaking.

SUMMARY AND CONCLUSIONS

Of 7,341 patients observed over a six and one-half year period, 3,090 were subjected to collapse for more than three months and 337 for less than three months, 330 had pneumothorax attempted and 3,584 were controls. Broadly, the results were twice as good with the treated patients as with the controls and better still as against the life expectancy of patients with open tuberculosis as revealed in the literature.

The matter of the controls is difficult, and results based on theoretical premises may be misleading. Because too many intangibles, imponderables and vari-

TABLE 11.—Air Embolism Versus Pneumothorax Treatments, Field Clinic Only

Year	Pneumothorax Treatments			Air Embolism	
	New Cases	Refills	Total Treatments	Number	Ratio of Treatments to Air Embolism
1931.....	126	1,250	1,376	3	459:1
1932.....	278	4,388	4,666	6	778:1

1937.....	469	22,851	23,320	1	23,320:1

ables are involved, we especially deprecate the measuring rod, based on morbidity and sanatorium mortality ratios. Collapse in widespread application is too new to affect the mortality tables conspicuously, to dominate morbidity and to influence the flux of summative and conflicting influences that swirl and eddy to actualize themselves in the composition of the death rates.

Collapse should have widespread application. Wherever possible, the unified plan is recommended: intramural collapse and extramural collapse, with reciprocity of function and interchange of patients, as indicated, between the two. Where the sanatorium ends the field clinic, expansile, inexpensive and elastic in its applicability to the need, begins. In small communities where a sanatorium is not practical, the addition of a few beds to the clinic will serve the purpose.

The relative values of the integers in the unified plan are seen in the results, a survival rate of 66.5 per cent for patients treated exclusively in the clinic, 75.9 per cent for patients treated exclusively in the Sanitarium and 84.9 per cent for those who had the advantages of combined clinic and Sanitarium treatment. The figures for the Sanitarium and clinic combined are the best, indicating a coordination of the field and institutional functions as the ideal basis for a plan of collapse.

The much mooted question of the initial treatment outside the institution did not seem to make a great difference; 70.6 per cent of the patients who received the initial treatment in the clinic were living, as against 78.1 per cent of the patients who received their first

injection in the Sanitarium. This observation, embracing a large number of cases, dissipates the myth that the initial treatment is purely an institutional prerogative.

Classified according to the types of treatment, the results of the investigation on the whole were better for combined collapse (two or more procedures) than for any individual measure. Collapse is viewed as a treatment sequence with an ideal indication and an optimum moment for each operation.

The results for the Negro, while not up to those for the members of the white race, are considered satisfactory. A gap in the mortality of 6 to 1 is reduced to a gap of 3 to 2, a development that suggests at least a partial solution for the lack of beds for Negroes throughout the country and invites speculation as to the possibilities of extramural collapse for Negroes.

The incidence of air embolism, twenty-eight accidents in 83,245 injections, compares favorably with the reports in the literature.

As a result of the investigation and of actual experience in the clinic and at the bedside, the officers and medical personnel of the City of Chicago Municipal Tuberculosis Sanitarium are convinced that collapse symbolizes a union of ends and aims, a double objective from a double function and a fine public health instrument as well as a medium of cure and rehabilitation, beneficial to any tuberculous patient with the indications but especially beneficial and even essential to the patient who, for lack of beds, cannot be given institutional care.

CARCINOMA OF THE LUNG SIMULATING INFLAMMATORY DISEASE

EMILE HOLMAN, M.D.

AND

PHILIP PIERSON, M.D.

SAN FRANCISCO

The mimicry of carcinoma by inflammation is a well recognized occurrence in intra-abdominal infections involving the stomach, colon or pelvic organs and occasionally the breast. Extensive inflammatory disease of the pelvis originating in a diverticulitis of the colon or in a salpingitis has simulated carcinoma so closely that a colostomy has been performed on the basis of a diagnosis of carcinoma followed by a surprising disappearance of the lesion. An extensive inflammatory process involving the cecum was mistakenly attributed to an inoperable carcinoma and to the prediction that the patient had but little time to live. Seven years later the patient returned for correction of a right inguinal hernia with no vestige left of the original palpable mass. Cancer may also mimic inflammation. Carcinoma of the liver not infrequently produces a high swinging fever indistinguishable from that due to an abscess and not correctly diagnosed except at laparotomy.

So many examples of this sort can be cited of the one lesion closely simulating the other that surgeons have found it wise and expedient never to make a diagnosis of carcinoma on appearance and feel alone but only on the basis of microscopic sections.

Exactly similar difficulties of diagnosis are presented by carcinoma of the lung, which not infrequently presents a clinical picture resembling pulmonary suppuration so closely that an exact diagnosis is possible

only by bronchoscopy, exploration or autopsy. Even at autopsy, as Graham suggests, a carcinoma of the lung may be overlooked entirely because of the overshadowing features of pulmonary suppuration.

This difficulty may account in part for the supposed recent increase in pulmonary neoplasms. It is highly probable that, in the past, patients ill from carcinoma

Fig. 1 (case 1).—Appearance (A) Sept. 12, 1931, and (B) Oct. 21, 1931, following resection of rib for exploration of a possible abscess. Tissue removed established the diagnosis of carcinoma, as did also the progression of the disease.

were mistakenly treated for tuberculosis, pulmonary abscess or pneumonia and the deaths were so recorded in the vital statistics. Until the last decade or two primary carcinoma of the lung was rarely encountered or, if encountered, was wrongly diagnosed. In 1912 Adler¹ collected 374 cases of carcinoma of the lungs and bronchi from all the literature and concluded that "primary malignant neoplasms of the lungs are among the rarest forms of disease." According to a recent statement by Graham,² textbooks a decade ago considered carcinoma of the lung as constituting less than 1 per cent of all carcinomas, while at the present time they represent more nearly 10 per cent of all carcinomas, an incidence comparable to carcinoma of the large intestine. Distressingly enough, several cases of carcinoma of the lung in small children have been reported recently, one in a boy aged 10 years,³ another in a child aged 7 years⁴ and a third in an infant aged 16 months.⁵ Whatever the explanation, it is certain that the diagnosis of carcinoma of the lung is being made more frequently, more accurately and, withal, more hopefully since lobectomy and pneumonectomy have withdrawn this disease from the limbo of hopelessness into the realm of cure.

Difficulties of diagnosis still exist, however, and the following cases are presented to illustrate that carcinoma may simulate suppuration so exactly that neither the clinician nor the radiologist can determine the exact nature of the disease. Bronchoscopy is indicated but does not always provide the solution. Certainly, any long unresolved pneumonia or persistent suppuration that does not yield to the usual therapeutic measures should be considered a case of probable neoplasm until proved otherwise.

CASE 1.—I. N., a Japanese farmer aged 44, entered the hospital Sept. 12, 1931, with a diagnosis of interlobar empyema following an illness the preceding May which had been diagnosed as lobar pneumonia. In May a rib had been resected for

5. Beardsley, J. M.: Primary Carcinoma of Lung in Child, *Canad. M. A. J.* 29: 257-259 (Sept.) 1933.

an empyema, but the wound closed spontaneously in six weeks. Following this closure he began spitting up pus, accompanied by cough and fever. Examination showed dulness and diminished harsh breath sounds without rales at the right apex, suggesting atelectasis. The temperature was 101 F., pulse rate 104 and respiratory rate 20. The white blood cells numbered 23,750 and the red blood cells 3,570,000, and the hemoglobin content was 49 per cent. The Wassermann reaction was negative. There was a small daily output of purulent sputum containing many cocci in chains, identified as *Streptococcus viridans*. Bronchoscopy revealed a little pus coming from the right upper lobe but no granulation tissue or obstruction of the bronchus. A roentgenogram (fig. 1) showed a heavy, roundish area of density with a fuzzy border in the midportion of the right upper lobe which was thought to contain an abscess. A rib was resected for a probable pulmonary abscess. Broken down pulmonary tissue was encountered which was later identified as of neoplastic origin. The patient died several months later of carcinoma of the lung.

CASE 2.—A. D. F., a housewife, first seen in January 1932, stated that five months previously she had had chills, fever, sore throat and "pneumonia" with as much as one cupful of "bad tasting" sputum daily. This gradually disappeared in three months, at which time another "cold" developed with return of sputum; which on one occasion contained 4 cc. of blood. The sputum contained no tubercle bacilli. A clear effusion was withdrawn on two occasions, followed by a dry tap. Examination showed hyperresonance over the left upper lobe with diminished to absent breath sounds over the lower two thirds of the left lung. Bronchoscopy for a probable intrapulmonary suppuration revealed carcinomatous tissue in the bronchus to the left lower lobe. She died a short time later.

CASE 3.—M. Z., a hotel clerk aged 55, entered the hospital complaining of recent diminution in vision and of asthma of fifteen years' duration, accompanied by a recent increase in cough and the appearance of grayish green sputum daily. He had had no hemoptysis or blood-tinged sputum. Pulmonary changes were minor in character except for those found in asthma and emphysema; namely, coarse rhonchi throughout, musical rales and squeaks and harsh, prolonged expiration. Roentgenograms showed a great deal of density in the region of the right lower lobe with many small cavities, which were interpreted as due to bronchiectasis (fig. 2). The clinical diagnosis included asthma, glaucoma, hypotension, ventral hernia and bronchiectasis. The eye was trephined for glaucoma, but

Fig. 2 (case 3).—Appearance showing (A) Nov. 19, 1930, probable bronchiectasis, (B) Dec. 17, 1930, an extension of the process with obstruction of the bronchus to the lower lobe due to tumor, revealed by bronchoscopy, and (C) Jan. 12, 1931, rapid spread of the disease accompanied by pleural effusion.

the progression of the pulmonary symptoms led to bronchoscopy and studies with iodized oil. On admission to the hospital his temperature was 39.5 C. (103.1 F.), pulse rate 100 and respiratory rate 34; the white blood cells numbered 9,400, the red blood cells 4,740,000, and the hemoglobin content was 76 per cent. Bronchoscopy revealed a primary tumor of the right main bronchus, obstructing the bronchus to the lower lobe. There was a rapid extension of the process radiographically and clinically. At autopsy a primary tumor at the bifurcation of the right bronchus was found, partially occluding the bronchi to the upper and lower lobes and completely closing the bronchus to the middle lobe. The carcinoma extended into

the pulmonary tissue, and metastatic deposits were found in the peribronchial and mediastinal lymph nodes. Small, healed tuberculous cavities were found at the apex of the right lung.

CASE 4.—J. M., a tile setter aged 56, on admission to the hospital complained of pain in the right shoulder for four months' accompanied by cough and some blood-tinged sputum in the past three weeks. There had been no loss of weight. The pulmonary signs included immobility of the right side of the chest, dulness and loud, sonorous respirations at the right apex and clubbed fingers. The roentgenogram revealed a heavy density at the right apex which was interpreted as of tuberculous origin. Examination of the urine was negative; the Wassermann reaction was ++. The red blood cells numbered 4,440,000, the white blood cells 14,400, with hemoglobin content of 70 per cent. Marked and rapid progression of all symptoms and signs led within three weeks to another roentgenogram (fig. 3), which revealed a destructive process involving the third rib. This was attributed to a neoplasm. He failed rapidly and died. At autopsy a carcinoma of the lung was found arising from an old tuberculous cavity with extension to the ribs and spine. Healed apical lesions due to tuberculosis were present on both sides.

Fig. 3 (case 4).—Appearance of an infiltrative lesion of the apex, first interpreted as tuberculosis but subsequently attributed to carcinoma when destruction of a rib was demonstrated. Patient died of pulmonary carcinoma.

CASE 5.—G. A. H., a man aged 77, a German, admitted to the hospital March 3, 1931, complained of pain in the right lower part of the chest and a productive cough of three weeks' duration. The patient was well nourished with some minor pulmonary changes in the right lower part of the chest, consisting of impaired resonance and many coarse rales which were interpreted as being due to a nontuberculous basilar infection. A roentgenogram (fig. 4), however, revealed a sharply rounded mass which was at first interpreted as being a tumor or possibly an echinococcus cyst. The temperature was 39 C. (102.2 F.), the pulse rate 130 and the respiratory rate 32; white blood cells numbered 15,040, red blood cells 3,750,000 with hemoglobin 75 per cent. The sputum revealed many gram-positive cocci. On the basis of a probable diagnosis of neoplasm, radiation therapy was begun but was promptly followed by a high fever, frequent coughing and considerable sputum. The diagnosis of tumor was now questioned and, accordingly, at the request of the medical division a rib was resected for a probable abscess or infected cyst. Instead a large broken-down neoplastic mass was found. The patient died after forty-eight hours. The autopsy revealed a large carcinoma with septic necrosis.

CASE 6.—W. T., a man aged 41, a molder, entered the hospital Feb. 13, 1930, because he had been spitting up blood for about four weeks. The patient had had a chronic productive cough of seventeen years' duration. After exposure to rain and chilling eight weeks previously, the cough and sputum had greatly increased, accompanied by the new symptoms of pain in the left side of the chest, chills and fever, night sweats, dyspnea, edema of the ankles and, subsequent to this, a bloody sputum. Weakness and loss of weight were also a part of the

recent picture. Physical examination revealed dullness and diminished breath sounds over the left lower part of the chest with many fine and coarse rales at both bases. A marked clubbing of the fingers was found. The temperature was 39 C. (102.2 F.) the pulse rate 120, the respiratory rate from 30 to 36, and a white blood cell count of 19,000. The urine showed a small amount of sugar, and the fasting blood sugar was 110 mg. per hundred cubic centimeters. The Wassermann

Fig. 4 (case 5).—Appearance of a man aged 77 in whom a tumor, or possibly an echinococcus cyst, was diagnosed. Operation and later autopsy revealed a large broken down neoplastic mass.

reaction was negative. Many sputum examinations showed numerous long chained streptococci and staphylococci but no tubercle bacilli. Bronchoscopy revealed that the bronchus to the left lower lobe was the source of the bleeding, but no tumor was seen. The first roentgenogram (fig. 5) was interpreted as follows: "The increased density in the left lower lobe is either a basilar tuberculosis or, more likely, a bronchiectasis." Injection of iodized oil, however, revealed an intrapulmonary excavation, irregularly triangular, more than 3 cm. in diameter. This was interpreted by the roentgenologist as an abscess. During the next few days a bloody pleural effusion developed on the left side, the fever remained elevated and he lost ground rapidly; he died March 8, 1930. At autopsy a primary carcinoma of the bronchus to the left lower lobe was found with metastases to the opposite lung, pleura, peribronchial lymph nodes, heart, liver, left kidney, right adrenal body and pancreas. There was evidence of a healed tuberculosis at both apexes.

The foregoing cases illustrate the ease with which a carcinoma of the lung may masquerade as an inflammatory process. Occasionally the mistake is reversed, and the pulmonary changes observed in a roentgenogram are interpreted as being due to tumor when in

Fig. 5 (case 6).—The increased density at the left base was first interpreted as being due to bronchiectasis, but after injection of iodized oil as due to an abscess. The arrow indicates the site of excavation of pulmonary tissue, which was found at autopsy to be due to carcinoma.

reality the process is due to calcified abscess or to silicosis. The following case illustrates this possibility:

CASE 7.—J. G., a man aged 58, entered the hospital March 11, 1930, because of numbness and weakness of the legs of one year's duration. For twenty-eight years he had been a quartz miner. In the three months preceding admission, shortness of breath and night sweats had developed. The pulmonary changes consisted of impaired resonance, diminished breath sounds and coarse rales over the right base and axilla. On the

basis of a blood examination, which revealed 2,860,000 red blood cells per cubic millimeter, 68 per cent hemoglobin, a color index of 1.1 and a complete gastric anacidity, a diagnosis of pernicious anemia with subacute combined sclerosis was made. The Wassermann reaction and analysis of the urine were negative. A roentgenogram (fig. 6) was interpreted as being due to tumor, with the qualified statement that the appearance could be caused by abscess of the lung with basilar infection and pneumoconiosis. A bronchoscopy revealed normal bronchi. Examination of the sputum was negative for tubercle bacilli. Under ventriculin and whole liver the blood improved to 4,640,000 red blood cells per cubic millimeter and a hemoglobin of 75 per cent. He was discharged to a home for the aged, where he died six months later. At autopsy there was marked pneumoconiosis, chronic pulmonary tuberculosis with acute exacerbation and tuberculosis of the spleen, liver, retroperitoneal lymph nodes and prostate. Sections of the lung showed the left lower base to be practically solid black fibrous tissue with a cavity 4 by 1 cm. in the center. There was no bronchial communication. In the right lower lobe was a cavity 7 cm. in diameter. No evidence of a malignant condition was found.

SUMMARY

The diagnosis of carcinoma of the lung has increased in the past twenty-five years from an incidence of 1 per cent to 10 per cent of all carcinomas encountered.

Fig. 6 (case 7).—Appearance in a quartz miner interpreted as presenting evidence of tumor at the right base but found at necropsy to be due to pneumoconiosis and chronic tuberculosis.

Its manifestations are protean and depend entirely on its location in the rather extensive pulmonary bed. When situated in the periphery of the pulmonary field, the first symptoms are referable to the thoracic wall; i. e., pain due to erosion of a rib or to an involvement of the intercostal nerve and vascular bundle, or to a pleurisy with subsequently a serous or bloody effusion. Such effusions should be aspirated, the fluid centrifuged and the cellular elements embedded in paraffin for microscopic sectioning and study.

Pain referred to the shoulder due to diaphragmatic involvement may occur, as may also paralysis of the diaphragm due to infiltration of the phrenic nerve. Horner's syndrome of narrowed pupil and ptosis may be due to infiltration of the cervical sympathetic nerve or upper thoracic ganglions by a pulmonary cancer. The most frequent symptom is cough, which follows the origin in or the invasion of the bronchial tree and is soon followed by blood-streaked sputum. Any persistent cough demands a roentgenographic examination, as does also the appearance of bloody sputum.

Not infrequently the presence of carcinoma is obscured by the overshadowing signs of infection. At certain stages in the development of pulmonary carcinoma it may present, owing to inflammation, all the

characteristics of an intrapulmonary abscess, of purulent bronchitis, of bronchiectasis or even of tuberculosis.

Atypical intrapulmonary lesions resembling inflammation but not entirely explained on the basis of inflammation are most frequently due to neoplasm.

Recent advances in surgical technic⁶ have made lobectomy and hemipneumonectomy successful and therefore imperative, whenever possible, in the care of pulmonary neoplasm. Early and exact diagnosis by every available means, including bronchoscopy, repeated roentgenograms, studies with iodized oil and aspiration biopsy,⁷ will insure better surgical results. The six cases reported are illustrative of the fact that pulmonary cancer simulates inflammation so closely that its presence may be overlooked because of the history and evidence of pulmonary infection.

MULTIPLE INTRACRANIAL TUMORS

A DISCUSSION OF THE RELATION OF MENINGEAL TO ACOUSTIC TUMORS AND A REPORT OF A CASE

W. JAMES GARDNER, M.D.

CLEVELAND

AND

OSCAR A. TURNER, M.D.

NEW HAVEN, CONN.

It has been recognized that some relationship exists between meningeal growths and those tumors which arise from the nerve sheaths or their components, but only recently has the nature of this association been given any considerable study. Most of the interest has evolved about that special form of generalized neurofibromatosis in which the central nervous system is predominantly affected. Mainly through the work of Harbitz,¹ Preiser and Davenport² and Schaltenbrand,³ generalized von Recklinghausen's disease has been long recognized as a familial disorder. Only recently, however, has it been shown that central neurofibromatosis

is also hereditary in that special form of the disease and may be transmitted as a dominant trait with little or none of the peripheral manifestations of the disorder.⁴

A special variety of central neurofibromatosis, bilateral acoustic tumors, has been described by Gardner and Frazier⁵ and Gardner⁶ and also established on a familial and hereditary basis. Further reference to this peculiar form of the disease need not be made here other than to state that additional clinical and pathologic evidence of the nature of this condition is in preparation at the present time.

The tendency for the acoustic nerves to be involved in central neurofibromatosis has been noted, and in most reported instances unilateral or bilateral acoustic tumors were present as part of the diffuse involvement of the cranial nerve sheaths by their specific tumors.⁷ There is usually some associated involvement of the meninges by their specific growths, but the degree varies considerably in the reported cases. The fact that gliomas as well as meningeal tumors are present in this condition has led to the concept that central neurofibromatosis is actually a disease process which involves all the binding tissues of the nervous system, including in its final picture specific tumors of the nerve sheaths, enveloping membranes and interstitial tissues of the central nervous system.

Unilateral (or solitary) acoustic tumors are relatively common and as far as can be determined at the present time bear no relationship to von Recklinghausen's disease or central neurofibromatosis. However, in rare instances they have been found, usually at autopsy, in association with other tumors, either of the central nervous system or elsewhere in the body.⁸ As an example of the association of a unilateral acoustic tumor with a meningeal growth in which von Recklinghausen's disease played no apparent part, the following case is briefly reported:

History and Examination.—A white woman aged 48, who complained of numbness of the face and deafness of the left ear when she was first seen in consultation at Mount Sinai Hospital, for about three years had experienced paresthesias and finally numbness in the distribution of the left trigeminal nerve. Marked impairment of hearing with the left ear had been present for about one year and recently had been associated with tinnitus. During the three weeks prior to hospitalization facial palsy on the left side of the peripheral nerve type had appeared. There had been some instability on walking, but this had not been prominent in the clinical picture. Nausea and vomiting had been absent.

Neurologic examination revealed paralysis of the left trigeminal nerve; this was virtually complete in both the motor and the sensory divisions. There was a questionable weakness of the left lateral rectus muscle. There was complete deafness in the left ear, and practically no response was obtained from caloric stimulation of the vestibular apparatus. The sense of taste was absent over the posterior third of the tongue on the left side. There was definite facial palsy on the left side, peripheral in type. Horizontal nystagmus was present on lateral gaze, but ophthalmoscopic examination revealed no papilledema. Lumbar puncture showed normal pressure but a marked increase

in the total protein content of the fluid. Roentgenograms showed questionable erosion of the apex of the left petrous bone.

The clinical diagnosis was tumor of the left cerebellopontine angle, but, because of the late appearance of the auditory symptoms, some doubt was entertained that the growth was an acoustic tumor.

Fig. 1.—Drawing from operative sketch. The smaller growth proved to be of meningeal origin, while the independent larger tumor arose in the cerebellopontine angle from the eighth nerve, which was incorporated in the inferior medial aspect of the tumor.

Operation.—A unilateral suboccipital craniotomy was performed. On elevation of the left cerebellar lobe, a small tumor measuring about 1.5 cm. in diameter was found to be adherent to the dura over the posterior surface of the petrous bone just lateral to the porus acusticus. The tumor had an irregular surface and was reddish gray. Further examination revealed a much larger tumor anterior and medial to the tumor first encountered (fig. 1). This second growth differed materially from the first. Its surface was smooth and yellow, and, except for its attachment to the margins of the porus acusticus, it was entirely encapsulated and independent of the more laterally situated smaller dural tumor.

The meningeal growth was curetted away and its base cauterized. An incision was then made into the capsule of the larger tumor, and the contents were removed with the aspirator and curet. The tissue, which was relatively avascular, was soft, canary yellow and easily removable. Traction on the capsule then revealed the seventh and eighth nerves incorporated in the inferior and medial aspect of the tumor. Since it was not possible to separate these, they were divided and the entire capsule was removed. The only point of attachment was to the margin of the porus acusticus, which was found to measure about 12 mm. in diameter. The fifth nerve was found to be greatly elongated and flattened and was dislocated forward. Apparently moderate traction had also been exerted on the sixth and ninth nerves by the growth.

The postoperative course was uneventful. On the second day there was evidence of returning function of the left trigeminal nerve, and one month later sensation over the face was practically normal. At this time the gait and Romberg reaction were normal and the nystagmus was practically absent.

Pathology.—The small meningeal tumor proved to be a fairly typical fibroblastic meningioma corresponding closely to Cushing and Eisenhardt's⁹ type III, variant 1. The tissue was composed of sheets of spindle-shaped cells with an abundance of cytoplasm and elongated nuclei with a moderately fine chromatin network.

No mitotic figures were observed. The cells tended toward a parallel disposition with considerable streaming and interlacing of cell bundles (fig. 2). Only an occasional psammoma body was observed. There was an abundance of small vessels scattered throughout the tissue, and about these an occasional whorl formation could be observed. No suggestion of nuclear palisading was seen in several sections of the tumor.

On microscopic examination the larger tumor proved to be the seat of considerable degeneration but was unmistakably of the type variously referred to as perineurial fibroblastoma, neurinoma and schwannoma. Small nuclear palisades could be identified in various fields, but none of these were very marked. However, the typical pattern of interlacing cell bundles could be recognized despite the extensive degeneration. The uninvolved tissue was dense and cellular and composed of parallel bands of elongated cells which had indefinite cytoplasmic boundaries. No mitotic figures were observed. In the degenerated areas the cytoplasm appeared granular and wide spaced and the tissue was edematous and reticular in appearance.

COMMENT

It is improbable that the meningeal tumor was in any way related to the atypical symptoms in this case. Such small meningeal growths are rare in the sub-tentorial region and when present give rise to symptoms only when they are so situated as to impinge on one or more of the cranial nerves, usually at their exit from the cranial cavity. They may be found, however, as a part of central neurofibromatosis or meningiomatosis. The latter condition by itself may or may not be a manifestation of von Recklinghausen's disease, and the differentiation here is not always easy. Cushing and Eisenhardt⁹ have described a case, previously recorded by Monrad-Krohn,¹⁰ of a small solitary meningioma which arose from the porus acusticus and produced localizing signs. The growth was removed at operation and on microscopic examination proved

Fig. 2.—The meningeal tumor. Note the fibrous character of the tissue and the tendency toward streaming and interlacing of cell bundles (Hematoxylin and eosin stain X 130.)

to be a fibroblastic meningioma containing numerous psammoma bodies. The literature on meningiomas of the cerebellar chamber has been reviewed by these authors.

The association of single acoustic tumors with one or more meningeal tumors has been reported from time

to time, and it is difficult in such cases to determine whether or not the condition is a form of von Recklinghausen's disease. It seems likely, however, that these cases, such as the one reported here, represent an incomplete or abortive form of the disease. Cushing and Eisenhardt⁹ have stated that the three conditions single acoustic tumor, bilateral acoustic tumor and generalized involvement of the cranial nerves appear to be gradations of the same malady and do not represent different disorders. Further study is needed on this subject, particularly in respect to the position of the single acoustic tumor.

RELAPSING FEBRILE NODULAR NON-SUPPURATIVE PANNICULITIS

REPORT OF A CASE

J. SAMUEL BINKLEY, M.D.

NEW YORK

The clinical syndrome of relapsing febrile nodular nonsuppurative panniculitis was first described by Pfeifer¹ in 1892 and by Gilchrist and Ketron² in 1916; it was reported in detail by Weber³ in 1925 and again by Christian⁴ in 1928, who added the term "febrile" to the terminology used by Weber. In 1933 Alderson and Way⁵ and Netherton⁶ reported cases. Subsequent reports by Weber⁷ and by Brill⁸ brought the total number of cases reported to eight. More recently, Bailey⁹ has reviewed the subject and added five cases that fit into the same general pattern.

The name is descriptive of the process, which is characterized by recurrent attacks of malaise and fever of varying degrees, associated with subcutaneous nodules (localized inflammation of the panniculus adiposus). The nodules may show various degrees of erythema, mottled brawny pigmentation and tenderness. They do not tend to suppurate and may undergo spontaneous regression, often resulting in localized atrophy and depressions in the contour of the skin. Residual areas of thickening may show cutaneous attachment. The syndrome is generally confused clinically with erythema nodosum, erythema induratum, nodular syphilis or migratory phlebitis.

Of the thirteen cases reported in the literature, eleven were in females and two were in males. Obesity has appeared to be a rather common feature. Christian's patient was seriously ill during the febrile attacks. One of the cases reported by Bailey presented a protracted severe course without remission and terminated in death. The confining nature of the attacks in the

reported cases seems to have depended on the stage in which the particular case was observed.

The histologic features of the excised nodules are fat necrosis and liquefaction, a mild degree of fibrosis and the presence of phagocytic cells for fat associated with multinucleated cells.

The etiology seems associated with infected teeth and tonsils and with rheumatism. Possibly the ingestion of bromides and iodides or other drugs associated with the treatment of acute and chronic rheumatic disease is a factor. Stockman¹⁰ in 1928 called attention to "chronic muscular rheumatism and panniculitis." Christian pointed out that the nodular form of the panniculitis described by Stockman resembles the syndrome in question.

In the reported cases the nodules were localized in the subcutaneous tissues of the extremities and the trunk. In the case here reported the nodules appeared first in the panniculus adiposus of the breasts, where they remained predominant. Similar subcutaneous nodules appeared on the extremities (fig. 1). Aspiration biopsy of the nodules (with a 17 gage needle) was productive of a thick greenish yellow mucoid material (sterile for organisms, including smears and cultures for tubercle bacilli). The same material was obtained from the nodules irrespective of their location and was reported by the laboratory as liquefied fat containing rare leukocytes. Microscopic examination of an excised nodule showed inflammatory fat necrosis (fig. 2). The material aspirated from the breasts was not confused with typical duct stasis and was identical with the material aspirated from the nodules on the extremities.

Menville¹¹ in his discussion of fatty tissue tumors of the breast, including lipomas, fat necrosis and xanthomas, concludes that at times such benign lesions cannot be differentiated clinically from malignant tumors. Menville made no mention of the syndrome in question.

In the case here reported some of the nodules during stages of regression, and particularly those which appeared in the breasts, were clinically quite similar to neoplasms. During the early stages the lesions in the breasts were soft, cystic and inflammatory. There was no discharge from the nipple. The lesions were not confused clinically with "plasma cell mastitis" described by Adair.¹² Subsequent regression of the lesions gave them a clinical similarity to multiple fibro-adenomas of the breast. Isolated nodules showed more or less cutaneous attachment not unlike that of cancer of the breast. Aspiration biopsy was of value in the differential diagnosis and a definite aid in establishing the similar character of the widely distributed nodules.

A preliminary review of the case histories in the breast clinic of the Memorial Hospital revealed that

in approximately 50 per cent of the cases listed under the diagnosis of traumatic fat necrosis¹³ there was no definite history of trauma. This observation has been mentioned by others who have contributed to the subject of traumatic fat necrosis. Perhaps half of such patients presented evidence of a definite extrinsic trauma or gave a history of a blow associated with

Fig. 2.—Section of the excised nodule showing fat necrosis and the presence of phagocytic cells for fat associated with multinucleated cells.

ecchymosis, or a trauma incidental to a hypodermoclysis received in the subpectoral region. There appears to be a repeated finding in the past histories of the patients who had no definite history of trauma, namely systemic infection. Obesity also seems to have been a rather common occurrence. Infections of the teeth and tonsils, rheumatism, cholecystitis, typhoid, pelvic inflammation and phlebitis were noteworthy. The histories of these cases are now being analyzed, and preliminary studies seem to favor a division of the group presenting clinical traumatic fat necrosis into (1) those cases in which a history of trauma to the breast is definite and (2) those in which there is no history of trauma. In the latter group the patients tend toward obesity and have pendulous breasts. Their past histories generally disclose evidence of chronic foci of infection. In the late stages the localized condition in the breast may show localized atrophy of the subcutaneous tissues, fibrosis, nodularity and cutaneous attachment. The histologic picture is that of inflammatory fat necrosis.

Further clinical studies may disclose that a definite disorder of the female breast, now obscure in the general classification of traumatic fat necrosis, may be best described as panniculitis of the breast or inflammatory fat necrosis. Such cases are not to be confused with the definite traumatic cases and in the future should be studied as a separate group with particular reference to evidence of panniculitis in other parts of the body.

The term panniculitis of the breast, therefore, is mentioned along with this case report of a more generalized and recognized syndrome (Weber-Christian) in an effort to reclassify certain disorders now rather obscure in clinical discussions of traumatic fat necrosis of the breast. All patients who have atypical nodules in the breasts and particularly those suspected of hav-

ing inflammatory fat necrosis should be carefully studied and examined for evidence of a generalized syndrome (Weber-Christian).

It must be pointed out that, if further studies reveal that there is such a condition as local panniculitis of the breast, then cases of panniculitis of the breast should be considered separate and apart from the case here reported unless the clinical syndrome of relapsing febrile nodular nonsuppurative panniculitis (Weber-Christian) is complete in all the more generalized features.

REPORT OF CASE

History.—A white woman aged 36, a native American housewife, admitted to the diagnostic clinic March 23, 1937, complained of lumps in the breasts of two months' duration. The family history did not reveal any history of tuberculosis, syphilis or other chronic infectious diseases.

The past history was significant in that she had suffered from intermittent attacks of rheumatoid arthritis. She had been hospitalized on several occasions during the previous six years because of painful joints associated with fever. She was never treated for symptoms referable to the heart during her stay in other hospitals. The patient stated that she had never had syphilis, though she gave a history of a macular cutaneous eruption associated with pruritus. The eruption would fade and disappear after a few days. There was no history of an excessive use of drugs. A blood Wassermann reaction six years previously was reported negative. Her menstrual history was essentially negative. Five months prior to admission to the clinic she had had an abortion performed. She had two children living and well.

Two months before admission to the clinic she first noticed a red spot and lump in her left breast. The region was not tender, yet the surrounding skin was swollen. Two weeks after the onset of the lump in her left breast a similar lump appeared in the right breast as an irregular, swollen soft area, covered with reddened skin. The localized swelling gradually subsided and the area became firm and nodular; the skin became darkened and bluish. Shortly after the onset of the second lump in the right breast two other lumps appeared in the left breast and were almost identical in their clinical course. At the onset the lumps appeared as localized areas of inflammation, then regressed without suppuration to form firm subcutaneous nodules with more or less attachment to the skin.

Fig. 3.—Higher magnification of section of the excised nodule.

Previously she had suffered from occasional attacks of fever; however, there was no history of recent episodes, generalized pruritus, bleeding from the mucous membranes, petechiae, cough, recent cutaneous rash or other significant systemic complaints. There was no history of trauma to the breasts, real breast pain or discharge from the nipple.

Two weeks before admission a lump very similar to the lumps in the breasts appeared in the calf of her right leg. No particular redness was noted. She believed that this lump was related to some form of varicose veins.

Surg.* 72: 188 (Aug.) 1920; A Further Report on Traumatic Fat Necrosis of the Female Breast and Its Differentiation from Carcinoma, *Surg., Gynec. & Obst.* 34: 521 (April) 1922; Traumatic Fat Necrosis of the Female Breast and Its Differentiation from Carcinoma, *Ann. Surg.* 80: 670 (Nov.) 1924.

A few days before admission she consulted her family physician because of an aching pain in her left ankle. She was advised to consult the Memorial Hospital because of the condition of the breast.

The patient stated that she bruised easily and that at times dark areas appeared beneath the skin which were tender and which gradually disappeared over a period of ten days.

Fig. 4.—Appearance of patient March 4, 1937 (on admission), showing multiple areas of nodular nonsuppurative panniculitis of the breasts.

Examination.—The patient was obese, weighing 178 pounds (81 Kg.), with moderate hirsuties of the face. She was an intelligent person.

The head and ears were normal; the pupils were round and equal and reacted to light and to distance. The nose, mouth and mucous membranes were normal. Most of the molars had been extracted because of apical abscesses; the residual teeth were only fair. The tongue was normal but the tonsils were embedded and infected. The pharynx and larynx were normal. There was no significant adenopathy of the neck; the thyroid was not palpable. The chest and the lungs were clear to percussion and to auscultation. There was some thickening of the skin at the anterior portion of the chest wall and of the girdle region. The blood pressure, was 160 systolic, 100 diastolic, with a regular rate and rhythm and no definite murmur. The liver and spleen were not palpable. There were scratch marks on the skin (the patient stated that there had been no itching). No abdominal masses were elicited. The groins were normal. There was a boggy cervix; the os admitted one finger; there was chronic endocervicitis but no erosion. The corpus was not felt; the adnexa were normal. The rectum was essentially normal.

The fingers tapered with no clubbing. There were moderate varicosities of the right lower extremity. In the middle of the right calf was a subcutaneous nodule, measuring 1.25 by 1 cm., not tender, firm and attached to the skin. There were macular cutaneous lesions a few millimeters in diameter scattered over the lower extremities (not typical of petechiae).

Local examination of the right breast revealed a slight bluish discoloration at 12 o'clock 8 cm. from the margin of the areola.

Palpation disclosed a firm mass, 2.5 by 3 cm. in diameter, which was not tender. There was cutaneous attachment with no definite dimpling. Transillumination disclosed a faint shadow. There was a tender node high in the right axilla, 1 cm. in diameter, which was movable. The nipple was normal, with no secretion.

There were three obvious deforming lumps in the left breast. The first, in the order of their appearance, was the one located in the lateral or upper outer quadrant and measuring 3 by 3 cm. There was a smaller cystic area located directly over this firm mass, 2.5 by 2.5 cm. in diameter. The skin over this area had a darkened, bluish discoloration. Passing counter-clockwise, from 2 o'clock to 12:30, a bulging, brownish mass measuring 3 cm. in diameter was observed. There was superficial fluctuation over this region, which was not tender. The induration extended in all directions, producing a mass with an irregular erythematous blush measuring 4 cm. in its longest diameter and extending to a point just outside the margin of the areola. This lesion was the most recent one and the overlying skin was red. Despite the redness there was no localized heat and but the slightest tenderness. This nodule measured 3 by 3 cm. and the central portion felt slightly fluctuant over an area measuring 2 by 2 cm. There was a node 1.5 cm. in diameter in the left axilla.

The provisional diagnosis was multiple bilateral cystic disease of the breasts with duct stasis. Infectious origin? Erythema nodosum?

Fig. 5.—Appearance Nov. 23, 1937 (after biopsy), showing regression of the nodules in the adipose tissues of the breasts.

The patient was referred to the breast department for further studies.

Follow-Up Notes.—March 24 the patient was seen in the breast department, where the condition was deemed unusual. A request was made for aspiration biopsy of the multiple areas.

The following day three areas in the left breast and two in the right breast were aspirated by means of a 17 gage needle. The nodule in the calf of the right leg was also aspirated. Thick, greenish yellow mucoid material was aspirated from the nodule in the leg. The same material was aspirated from the

nodules in the breasts. The laboratory reported that all specimens showed thick mucoid material with rare leukocytes. They were negative for acid-fast bacilli, nor was there any suggestion of tubercle structure. Culture yielded no growth on the fourth day. (There was no growth on the eighth day.) Stained specimens were negative for organisms.

March 29 another typical area was discovered in the left popliteal fossa; aspiration was productive of similar material. The laboratory report was "liquefied fat." There were no organisms on stained smear; cultures yielded negative results. The cultures taken previously were still negative. The absence of organisms and the failure of cultures to yield results would suggest, of course, that this might be part of the rheumatic picture.

April 1 the patient was presented at the regular staff conference for general discussion and opinions. It was suggested that an area in the breast be excised for biopsy.

April 9 the patient was admitted to the hospital for a local excision of a typical area in the breast. On admission she gave a history of malaise and chilly sensations of several days' duration. The admission temperature was 100.8 F., pulse 100, respiratory rate 20. The general examination was essentially unchanged except that there appeared to be some regression in the size of the nodules.

The results of laboratory examinations revealed the following: Urinalysis was negative. Blood smear showed a normal differential; hemoglobin 85 per cent (Tallqvist), red blood cells 4,444,000, white blood cells 13,000. Blood sugar was 83.8 mg. per hundred cubic centimeters. The Wassermann reaction of the blood: alcohol negative, cholesterol negative; Kahn reaction of the blood, negative. Agglutination tests on the blood for typhoid, paratyphoid A and B, Brucella and typhus were negative.

April 12 under cyclopropane anesthesia a radial incision was made over the mass in the upper inner quadrant of the right breast. The mass was removed intact. There was no connection in the form of ducts between the mass and the breast tissue. The wound was closed with a small rubber tube drain.

Histologic examination of the excised specimen was reported as "inflammatory fat necrosis." Postoperatively the wound continued to drain a thin brownish mucopurulent material. The wound was irrigated. Tissues refused to fill in the dead space and the wound was opened and allowed to heal by second intention. The patient was discharged April 25. Smears of the wound May 4 revealed streptococcal contamination.

June 21 another nodule 1.5 cm. in diameter was noted in the left breast at 12 o'clock on the dial 6 cm. from the nipple and another new nodule at 7 o'clock.

A nodule 1 cm. in diameter appeared in the subcutaneous tissues of the lateral aspect of the right knee, another 2 cm. in diameter was found in the right groin. A small typical nodule was located in the lateral aspect of the left elbow. Several of the earlier nodules in the breast had regressed.

July 1 the subcutaneous nodules in the breast and the extremities showed marked regression. The patient complained of swelling in both knees. There was slight local edema. The heart rate and rhythm were normal and there was no murmur. The patient was placed on salicylates.

November 22 in the left breast were two residual nodules, the largest 15 cm. in diameter, the smallest 0.5 cm. The rest of the nodularity had regressed.

Jan. 3, 1938, the patient was presented at the staff conference as representing the syndrome of relapsing febrile nodular nonsuppurative panniculitis (Weber-Christian disease).

January 11, chemical analysis of the blood showed total blood lipids 644 mg. per hundred cubic centimeters of serum, phospholipids 144 mg., free cholesterol 55 mg. and cholesterol esters 122 mg. These figures are regarded as within the normal range according to the values of Van Slyke and his co-workers.

One week previous to February 7 she noticed a rather inflamed erythematous area over the left crest of the ilium which had progressively enlarged. The area was firm, subcutaneous and only slightly tender. The induration involved a portion of the girdle fat and measured 7 by 4 cm. The area appeared more hemorrhagic than the lesions observed in the breast, but the general appearance was much the same and appeared to represent nonsuppurative panniculitis.

April 1 the area of panniculitis in the left groin had regressed. The induration was said to have remained about three weeks after the initial appearance. There was no suppuration. Three weeks previously another similar nodule had appeared on the inner aspect of the right arm. After ten days this area also regressed without suppuration. The patient had had no chills or fever during the previous three months and was free from pains in the joints. Aspiration of a small residual nodule in the left breast was productive of 0.5 cc. of liquefied fat. The patient was to return in one month for observation.

SUMMARY

In the case of relapsing febrile nodular nonsuppurative panniculitis here presented the first noticeable nodules appeared in the fatty tissues of the breasts.

The patient had a definite episode of moderately severe relapsing fever associated with the appearance of multiple nodular nonsuppurative areas of panniculitis. Her family physician discovered lumps in her breasts which he believed resembled cysts or possibly neoplasms.

During her observation in the breast clinic of the Memorial Hospital she was never actually confined to her bed except for a short period for clinical studies. The nodules regressed during a period of three weeks to a month from their initial onset, without suppuration but with residual evidence of thickening and persistent cutaneous attachment in some instances. Sporadic new nodules made their appearance on occasions generally associated with a mild malaise. Two such episodes of minor importance occurred during the year of follow-up visits to the clinic. During each minor attack areas of nodular panniculitis appeared, associated with relapsing fever, chilly sensations and mild pains in the joints.

The laboratory studies, including chemical analysis of the blood lipids, disclosed no unusual changes. In this case the etiology seemed associated with rheumatism.

The case calls attention to the fact that localized panniculitis of the female breasts probably occurs separately and apart from the general syndrome here described. Preliminary studies of a group of patients seems to indicate that nonsuppurative panniculitis of the breasts may produce an inflammatory fat necrosis that resembles the definite traumatic fat necrosis so often confused clinically with cancer.

NOTE.—Recent late reports by Cummins and Lever¹⁴ and by Shaffer¹⁵ are highly suggestive of an addition of three more cases to the literature. Shaffer's case differed in that the lipolytic response in the subcutaneous fat appeared more active than the fibroblastic response.

CONCLUSIONS

1. Nonsuppurative subcutaneous nodules, occurring in and about the female breasts, should arouse suspicion of the clinical syndrome of relapsing febrile nodular nonsuppurative panniculitis (Weber-Christian disease).

2. Aspiration biopsy, though not diagnostic, may prove helpful in leading to the recognition of the similarity of widely distributed nodules.

3. In certain stages the nodules may be confused clinically with various subcutaneous tumors, and because of this fact the clinical syndrome should be called to the attention of the general surgeon.

METHODS FOR CONTROLLING SCHISTOSOME DERMATITIS

STERLING BRACKETT, M.A.

MADISON, WIS.

It was shown by Cort¹ in 1928 that a type of dermatitis is produced by the penetration of certain larval flukes, schistosome cercariae, into the human skin from water. This disease, which is known by various common names such as "swimmer's itch" or "water rash," was given the name schistosome dermatitis by Cort, and he suggested at that time that a dermatitis produced by the penetration of these cercariae might have a widespread occurrence. This has proved to be the case, for reports of the presence of "swimmer's itch" in other regions both in North America (Minnesota² and Manitoba³) and in Europe (Wales,⁴ Germany⁵ and France⁶) soon appeared. While a number of reports, summarized by Cort,⁷ show that the disease is scattered over the United States, it seems to be most prevalent in the lake regions of the North Central states, including Minnesota, Wisconsin and Michigan, and in the adjoining Canadian province of Manitoba. Besides furnishing a favorable habitat for the snail hosts of the cercariae, these lakes are popular for bathing, thus bringing man into direct association with the causative organism.

Because of its transitory nature, schistosome dermatitis is not serious except in the occasional cases of extreme exposure, but it is important in the United States and Canada because it is sufficiently annoying to be an economic detriment in any resort area where it occurs. In recent years in Wisconsin it has attracted attention and apparently injured resort business to such an extent in some localities that the Wisconsin State Board of Health in cooperation with the University of Wisconsin⁸ has undertaken to study the factors influencing its occurrence with the hope of controlling it. Investigations during 1938 and records from previous years indicate that, with the exception of one or two localities, the seriousness of this disease in Wisconsin has been exaggerated and that usually only a few cases actually occurred where many had been reported to the board of health. The cercariae have nowhere in Wisconsin been found in exceptional abundance, but of course they may become abundant in years to come. That cases of this disease may actually occur in great numbers in some places is indicated by several records

in the literature. McLeod⁹ and Swales⁹ reported it as afflicting a great many bathers at Clear Lake in Manitoba, and investigations in Michigan⁷ show that schistosome dermatitis is widespread and of common occurrence in this state. In addition, in an unpublished record Cort has pointed out that the condition was unusually severe in the summer of 1938 at several lakes in the northern part of the southern peninsula of Michigan.

This paper presents the results of the investigations in Wisconsin so that they will be available for use in future work, since the control of schistosome dermatitis will undoubtedly receive increasing attention.

Some preliminary remarks concerning the nature of the parasite, its distribution and its host relationships will make the subsequent discussion clearer. Four species of schistosome cercariae in Wisconsin and neighboring areas have been shown capable of producing dermatitis. These are *Cercaria elvae*, found in the snails *Lymnaea stagnalis* and *Stagnicola palustris*; *Cercaria stagnicola*, found in the snail *Stagnicola emarginata*; *Cercaria physellae*, found in species of the snail genus *Physa*, and the cercaria of *Schistosomium douthitti*,¹⁰ found in marsh-dwelling varieties of *Lymnaea stagnalis* and *Stagnicola palustris*. Of these four, the life cycle of only the last one is known. It is completed in meadow mice and possibly in muskrats. However, it is the three whose cycles are unknown that are the most important causes of dermatitis on swimming beaches.

Evidence such as the distribution of the cercariae and the fact that they generally appear for only a few weeks each summer seems to indicate that the life cycle of these three species may be completed in migratory birds that have dropped eggs of these worms into the lake waters during their spring migration northward. In fact, adult schistosome worms have been found in blue-winged teal, herring gulls¹¹ and several species of diving ducks¹² in Canada by McLeod, and I have found a high percentage of blue-winged teal from certain Wisconsin areas infested with the schistosome *Pseudobilharziella quercudulae* McLeod, 1937. The fact that several species of cercariae and snails may be involved in outbreaks of dermatitis is important in any consideration of control. Since different species of snails have different habits and are found under varying conditions, the methods of attack cannot always be the same. Some snails are found in small pools that can be easily treated with chemicals, while others live in larger lakes, where the whole body of water cannot be treated. In the latter case the snails may be successfully attacked if they occur in limited beds, but others in larger lakes are so widespread that to kill them would be very difficult. Under favorable conditions schistosome dermatitis can probably be controlled most effectively by destroying the snail host. This phase of the problem will be considered first.

RESULTS OBTAINED WITH COPPER SULFATE

In all the attempts to kill snails of which I know, copper sulfate has been used. This is probably due to the experience gained in the use of this compound for the treatment of drinking water reservoirs, where it was

From the Department of Zoology, University of Wisconsin, and the Wisconsin State Board of Health.

Acknowledgment is made to the Bureau of Sanitary Engineering of the Wisconsin State Board of Health for assistance and cooperation, to District Sanitary Engineer Mr. Charles Senn for the active part he took in the field experiments at Plum Lake and to Dr. W. W. Cort of the School of Hygiene and Public Health, the Johns Hopkins University, Baltimore, for suggestions and for permission to refer to some unpublished work.

found that copper sulfate was lethal to many organisms besides the plankton.¹³ The first attempt to control schistosome dermatitis by the use of copper sulfate to kill the snails was at an artificial lake in one of the municipal parks of Cardiff, Wales,¹⁴ shortly after the cause of this disease was discovered.¹ Many snails were killed with an initial dose of copper sulfate at a concentration of 2 parts per million and the outbreak was stopped. However, the dermatitis reappeared and it was found necessary to treat the lake again at regular intervals. After each successive treatment more snails were found dead, indicating that at least some of the snails resisted one or several exposures to the chemical.

The successful use of copper sulfate at Cardiff led Cort and his co-workers (unpublished record) to use it in an attempt to control the dermatitis at a beach on Little Traverse Bay of Lake Michigan, close to Harbor

have been a reasonably high concentration. Many snails were killed and the outbreak of dermatitis was checked. Here one application appeared to be successful, but I made an investigation of the area in the summer of 1938 which revealed the fact that the snail population had again been built up to a high level. However, no outbreaks occurred during that summer because the snails did not become infested.

It is to be noted that the three areas where copper sulfate has been used with apparent success have two significant characters in common: (1) they are all small and isolated bodies of water and (2) they are important primarily for bathing. At Cardiff and Beaver Dam the pools are artificial, and at Harbor Springs the area involved is a small, isolated bay almost completely cut off from the main body of water. In all these areas the danger of killing fish was a minor consideration or did not exist. As far as is known there are no other records of the successful use of copper sulfate to kill snails in the control of schistosome dermatitis. It is true that Swales suggested the use of this substance at Clear Lake, Manitoba, but results have apparently been similar to those described for Plum Lake, Wisconsin.

Surveys of the outbreaks of schistosome dermatitis in Wisconsin showed that, with the exception of the Beaver Dam area and one river area, the trouble occurred in lakes so large that it would be difficult to treat the whole volume and where the possibility of killing fish must be considered. In these larger lakes chemicals may be used successfully if the snails are concentrated in limited beds in shallow water so that only small areas of the lake need be treated. However, if the snails are widely scattered the possibility of killing them is undoubtedly out of the question. Plum Lake, Wisconsin, where the beach snail *Stagnicola emarginata* occurs in restricted beds, was chosen for a trial of the effectiveness of using a chemical on a limited part of a whole lake. Copper sulfate was applied to a bed of snails which was found on the beach of a summer resort where schistosome dermatitis had been very troublesome for several summers. The first application, calculated to be a concentration of copper sulfate of 1 part per million, killed quite a few snails but many survived and the cases of dermatitis did not stop. Another application of about 6 parts per million killed more snails but many were still alive the next day. In addition quite a number of perch fry were killed close to shore, but no larger fish were harmed. Two more applications of copper sulfate, in concentrations of from 6 to 10 parts per million, killed all the young snails on the beach, although some adults still survived. Occasional cases of dermatitis subsequently occurred, but since beds of infested snails were present in other parts of the lake, even within 300 yards of this experimental area, cercariae may have been drifting in on water currents. This experiment gave results similar to those obtained in the three areas previously described, that is, it was apparent that copper sulfate must be used repeatedly or in relatively high concentrations in order to produce a significant reduction in a snail population. In addition it was definitely shown that if the distributing equipment is of a type that does not insure immediate dispersion of the chemical, small fish at least are killed with concentrations that are not completely effective in eliminating snails. It is also suggested that cercariae drifting in from other parts of the lake may continue to give trouble on a beach of this nature.

Experimental schistosome dermatitis, showing protection obtained from brisk rubbing of exposed areas. The left foot was wiped immediately after removal from infested water.

Springs, Mich. This area consists of a small bay not over 200 yards in its greatest diameter nor deeper than 8 feet and practically cut off from the main lake by sand bars that reach almost to the surface. Relatively large quantities of the chemical were used in several applications before the snails were completely controlled. A third and also unpublished record of the successful use of copper sulfate concerns a small artificial pool made by damming a stream near Beaver Dam, Wis., for recreational bathing. When "swimmer's itch" suddenly broke out there in 1937, the district sanitary engineer of the Wisconsin State Board of Health suspected that it was schistosome dermatitis when he found that the pool had a large snail population. He recommended the application of copper sulfate, and enough of this chemical was introduced to make what must

14. Cort, W. W.: *Studies on Schistosome Dermatitis: I. Present Status of the Subject*, *Am. J. Hyg.* 23: 349-371 (March) 1936.

The evidence accumulated from the reports recorded and from others¹⁵ concerning the killing of fish with copper sulfate, combined with the results of some preliminary laboratory experiments carried on by me and by the conservation department and the state board of health of Wisconsin, lead to the conclusion that copper sulfate is not the most suitable chemical to use in the control of schistosome dermatitis. Although it does kill snails it possesses two serious disadvantages, namely (1) under certain conditions it is dangerous to fish life and (2) it is rapidly lost from solution. Copper sulfate is lost in three ways: (1) by natural run-off or by convection and wind currents, (2) by forming a combination with organic matter and (3) by forming an insoluble carbonate in hard water. At least the first and third methods of loss must always be considered as variable factors, since the dilution of the chemical by the mixing effects of wind currents in larger lakes is obviously important and since the water most favorable for snails important in this disease is of varying hardness and alkalinity. This rapid loss of copper sulfate from solution is very important, because experiments show that snails must remain in a 1 part per million solution for a period longer than from seven to twenty-four hours, depending on such conditions as temperature, or they can revive in the presence of fresh water. It is evident then that no recommendation can be given for determining the amount of copper sulfate to be used without first determining the factors involved in the individual case. These factors can be determined only by an experienced person, an important point to be considered in any extensive efforts to control schistosome dermatitis.

RESULTS OBTAINED WITH COPPER CARBONATE

In the search for a more suitable compound for killing snails, copper salts were found to have by far the most lethal action, while many other compounds in reasonable dilutions had no effect at all. Of the copper salts copper carbonate ($\text{CuCO}_3 \cdot \text{Cu}(\text{OH})_2$) seems to be the most promising. Because of its low solubility it is possible that even in the presence of an excess of the compound there might be enough copper in solution to kill snails but not enough to endanger fish life. Experiments in the laboratory and field support this supposition. It has been conclusively shown that copper carbonate does kill all the important species of snails within two to five days. In addition fish are completely unaffected in water on the alkaline side, of p_H 7 in aquariums in which there is enough of an excess of copper carbonate to form a noticeable deposit on the bottom and in which the snail populations have already been wholly killed by the chemical. While copper carbonate may cost more per pound than copper sulfate, it may not be more expensive to use, since less of it will probably be effective and it can be applied with less labor.

The following experiments illustrate the action of copper carbonate and indicate its possibilities:

EXPERIMENT 1.—A 2 parts per million solution of copper sulfate in distilled water was compared with a solution in which there was an excess of copper carbonate. Snails of the species *Stagnicola emarginata* were killed in both solutions but not in the control of untreated water. Several minnows lived in the control aquarium and in the one containing copper carbonate but died in a few hours in the one with copper sulfate.

EXPERIMENT 2.—Ten large *Lymnaea stagnalis* snails were killed in saturated copper carbonate while the controls were unharmed.

EXPERIMENT 3.—Ten large *Lymnaea stagnalis* snails were put in each of three aquariums. In the first a screen was arranged in such a way that the snails could not come in contact with or ingest the copper carbonate sprinkled on the bottom but were exposed to the copper that was in solution. They were fed lettuce. In the second aquarium the copper carbonate powder was sprinkled over the lettuce. At the outset the snails were seen eating the chemical. The third aquarium was a control containing only untreated water and lettuce. The snails in the first two aquariums were soon affected. This was best determined by noting that these snails stopped eating their lettuce while the controls continued to eat. In three days almost all the snails in aquariums 1 and 2 were dead and in five days they were all dead, while the controls were still living normally. This indicates that copper carbonate in solution is as lethal as when it is ingested or comes in direct contact with the snails.

EXPERIMENT 4.—Copper carbonate was applied to a shallow area in Plum Lake, Wisconsin, 100 by 75 feet in dimension and well populated with *Stagnicola emarginata*. This area was in all ways similar to the one treated with copper sulfate. One treatment with an amount calculated to be about four times enough to saturate the water was done. So far as could be determined this treatment seemed to be 100 per cent effective in destroying the snails. Comparison with the area treated with copper sulfate indicated that copper carbonate is much superior. Another area on the same lake treated with copper carbonate gave the same results.

EXPERIMENT 5.—After several preliminary experiments which showed that alkaline lake water with an excess of copper carbonate did not affect fish, the following critical experiment was performed: Four aquariums were set up. In two the water was adjusted to a p_H of 6.6, and in the other two the lake water, with a p_H of about 8.1, was left unchanged. Fifteen young sunfish and bluegills were put in each aquarium. Copper carbonate calculated to be approximately 200 times enough to saturate the water was added to one of each of the two sets. The test lasted three days at a temperature that was uniformly about 25 C. In the water with a p_H of 6.6 containing copper carbonate the fish started dying within five hours and continued to die throughout the experiment. Ten fish had died when the experiment was closed. Of the remaining five, four had been transferred to fresh water when they first showed signs of being affected by the chemical and were revived, while a single fish resisted the chemical to the end of the experiment. This clearly indicates that in acid water copper carbonate may be dangerous to fish life but that fish can revive if they reach untreated water before they are too far gone. On the contrary, not a single fish was killed by the copper carbonate in alkaline water with a p_H of from 7.9 to 8.1. Fortunately snails known to be important in the spread of "swimmer's itch" have been found only in alkaline water, in which copper carbonate seems definitely to be unharmed to fish.

COMPARISON OF THE PROPERTIES OF COPPER SULFATE AND OF COPPER CARBONATE

Since from the evidence presented it seems reasonably safe to conclude that copper carbonate may be a suitable chemical to use for killing snails in the control of schistosome dermatitis, it becomes significant to compare its properties with those of the only other chemical used at all extensively for the same purpose, namely copper sulfate. Copper carbonate if present in sufficient quantities to maintain a saturated solution for several days effectively kills snails of the important species but does not injure fish, while copper sulfate may kill fish under conditions in which snails are not completely destroyed. Because of the relatively low solubility of copper carbonate and the fact that the normal range of conditions found in lakes suitable for the snail hosts of schistosome cercariae does not alter

15. Smith, M. W.: The Use of Copper Sulfate for Eradicating the Predatory Fish Population of a Lake, Tr. Am. Fisheries Soc. 65: 101-113, 1935.

its effect, rules can be established for determining the amount that should be added to the water, so that it can be used by relatively unskilled persons. On the other hand, copper sulfate is so affected by normal changes in lake conditions that it should be used only with expert supervision. This difference is of primary importance, especially where any extensive treatment is concerned. In addition, even though copper sulfate is used expertly enough to avoid the danger of killing fish, its reputation in this respect is such that its use must be constantly defended against criticism. Also, even with adequate supervision there seem to be enough uncontrollable factors to prevent its being completely effective, so that it must be applied a number of times. Since copper carbonate can safely be applied in excess, one treatment will usually suffice unless the snail population is rebuilt by some unusual type of influx from outside the area. From these comparisons I believe that the disadvantages of copper sulfate for killing snails outweigh the advantages, and until further evidence is obtained I suggest that copper carbonate may be the most effective, easiest and safest chemical to use in the control of schistosome dermatitis.

The following rule may be used in determining approximately the amount of copper carbonate to be added to the water: Calculate the number of cubic feet of water overlying the area to be treated and multiply this number by 0.0003 pound. This will give approximately the number of pounds of the copper carbonate necessary to saturate the volume of water in question. In our experiments so far, my associates and I have used about four times this amount in order to secure an excess which would serve as a constant source of copper ions. This estimate is merely a guess at the amount of excess necessary, but it seems to be satisfactory. If the material used is a commercial grade which is not 100 per cent copper carbonate, the difference will have to be accounted for by using a proportionately larger amount. There is no reason why the most inexpensive grade obtainable should not be used unless it contains dangerous impurities.

KILLING THE CERCARIAE

It is emphasized again that an attack on snails may be successful or feasible only in relatively small bodies of water or where the snails are concentrated in definite beds. In the latter event the bed of snails causing the trouble need not necessarily be right on or adjacent to the area afflicted but may be some distance away. However, if, as in a number of places in Wisconsin, the snails are too widely distributed to be successfully killed with chemicals, another method of preventing outbreaks of dermatitis suggests itself, namely that of killing the cercariae. This has the obvious disadvantage of being a very temporary measure, for a new swarm of cercariae may emerge each day during certain periods of the summer. Outbreaks in lakes in which the snails are widely distributed have not been extensively studied, because the snails in these lakes were not heavily infested with cercariae during the summer of 1938. There is evidence at hand, however, to suggest that a particular beach may not be troubled every day during the critical period. Very warm days with a slight onshore drift seem to favor the occurrence of the disease. Consequently, if methods could be devised for detecting or predicting the appearance of cercariae on a beach, the water would need be treated only when they are present.

In laboratory experiments schistosome cercariae have been shown to be remarkably resistant to a number of chemical compounds in reasonable dilution but extremely sensitive to high dilutions of formaldehyde. In a 0.03 per cent solution (solution of formaldehyde, U. S. P., is used as 100 per cent) schistosome cercariae were all killed in one minute or less. A 0.005 per cent solution killed them in five minutes, and a 0.0025 per cent solution killed them in from ten to fourteen minutes. Unfortunately, because of the scarcity of suitable outbreaks of dermatitis in the summer of 1938, formaldehyde has not been tried in the field. Nevertheless, the following suggestions for its use are made: In lakes where it seems advisable to attempt to kill the cercariae to control outbreaks of schistosome dermatitis, a formaldehyde solution might be sprayed on the surface of the water of the bathing beach with some type of insecticide sprayer. Studies of the cercariae indicate that they become concentrated at the surface of the water and that two of the species may also cling to floating weeds and debris. Consequently, it seems probable that only the upper layers of water need be considered in the treatment. The following method for determining the amount of the solution to be used is recommended: Determine in square feet the surface area of the water to be treated and divide this by 1,600. This will give the number of gallons of solution of formaldehyde necessary to make the top centimeter of water into a 0.25 per cent solution. When this amount of chemical diffuses into a layer of water 8 cm. thick, it will give a 0.03 per cent solution, which has been shown capable of killing cercariae in one minute. Even with further dilution of the substance, cercariae probably will still be affected. In order to obtain a more even distribution of the chemical, it should probably be diluted three or four or more times before being sprayed. Best results will probably be obtained by spraying in the morning before the beach is used. It has been shown that the cercariae emerge at daybreak,¹⁶ and unless they drift in from great distances, the day's crop may be killed with one treatment at 8 or 9 a. m. The water should not be disturbed any more than necessary during the spraying and should be left undisturbed for about one-half hour afterward. Then, to obviate any danger to the bathers from the formaldehyde, a motor boat driven back and forth over the deeper parts and a row boat rowed in the shallower parts would mix the chemical with the water sufficiently to reduce its concentration down below any possible danger point. It is emphasized here that extreme care must be used with this substance to prevent injury to bathers.

A SIMPLE PROPHYLAXIS AGAINST SCHISTOSOME DERMATITIS

As mentioned earlier in this paper, records indicate that in a number of places in Wisconsin only a few people are troubled each year with schistosome dermatitis. In these places even if chemicals could be used to control the snails or the cercariae, the number of people involved might not justify the expenditure necessary. Consequently, some method was sought for protecting bathers before they enter or of treating them after they leave infested water to prevent an attack.

Since different persons have had some success in preventing schistosome dermatitis by rubbing the skin with such substances as alcohol, kerosene, gasoline, or soap immediately after bathing in infested waters, this

16. Cort, W. W., and Talbot, S. B.: Studies on Schistosome Dermatitis: III. Observations on the Behavior of the Dermatitis-Producing Schistosome Cercariae, *Am. J. Hyg.* 23: 385-396 (March) 1936.

point was investigated with the hope of finding some easy method of prophylaxis for use where other methods of control are out of the question. Preliminary experiments suggested that the simple mechanical process of rubbing the skin was the effective agent in this procedure rather than the action of any chemical compound. Consequently a number of tests were made by immersing parts of the body of an experimental person, known to be susceptible to the disease, in water containing schistosome cercariae of the proper species. After certain periods of exposure, the parts were removed and an area rubbed thoroughly, briskly and with a towel, while the water was allowed to evaporate from a control area. In all cases typical lesions appeared on the control area, where the water evaporated, while fewer or no lesions appeared on the area that had been rubbed dry immediately on removal from the water. The accompanying illustration shows the results of a final, critical test. For this test, numbers of *Cercaria stagnicola* that had recently emerged from beach snails *Stagnicola emarginata* were placed in a pail of water. Both feet of the experimental subject were immersed in the water for ten minutes and then removed. The left foot was wiped dry, while the other was allowed to dry by evaporation. Severe itching was soon felt on the right foot but not on the left. By the next day about 120 lesions could be counted on the right foot, which had not been wiped, and only one on the foot that had been wiped. From this study it is concluded that schistosome cercariae penetrate the skin of human beings largely if not entirely when the water is evaporating.

This idea is borne out by the observation that the worst dermatitis occurs in children who play in shallow water, where wet parts of the skin are constantly being exposed to evaporation, or in people going in and out of the water frequently. The friction of the towel apparently destroys the cercariae before they have had a chance to penetrate into the skin. Thus, if a bather remains completely immersed until he is through swimming and thoroughly wipes himself immediately on coming from the water, he may completely protect himself from an attack of schistosome dermatitis or at least materially decrease the extent of such an attack. It is emphasized that the rubbing must be done immediately, particularly on warm or windy days, when the water on the skin would evaporate rapidly. While this method of prophylaxis will not prove to be completely effective it will undoubtedly be of considerable value in many places. In addition it has the advantage of being simple and easy and involves no expense.

SUMMARY

Copper carbonate is recommended as a chemical to replace copper sulfate for killing snails in the control of schistosome dermatitis because it may be used safely by relatively unskilled persons and one application may be sufficient. Chemical treatment for destroying snails may be effective only in small isolated bodies of water or in larger lakes where the snails are concentrated in beds. In larger lakes where the snails are too widely distributed to be destroyed, it is suggested that the cercariae may be killed daily with solution of formaldehyde if enough cases of dermatitis occur to justify the procedure. This substance must be used with extreme care. Where these methods of control are unavailable or impracticable or the number of cases of dermatitis too few, vigorous wiping immediately after coming from infested water may be a useful prophylaxis.

HEREDITARY OSTEOCHONDRODYSTROPHIA DEFORMANS

A FAMILY WITH TWENTY MEMBERS AFFECTED
IN FIVE GENERATIONS

A. WILMOT JACOBSEN, M.D.

BUFFALO

The term osteochondrodystrophy describes a developmental disease of the skeleton which produces many different clinical pictures. It is a defect, often familial, in the orderly growth of ossifying cartilage, which may result in almost complete arrest or in any degree of partial arrest of endochondral ossification. The resulting deformities will depend on what pattern the perverted cartilage growth follows. It may take the form of enchondromas remaining as multiple islands of cartilage cells within the epiphyses or shafts, of multiple cartilaginous exostoses (chondrodysplasia) in which outgrowths appear at the line of enchondral ossification between the epiphyses and diaphyses, of chondromas predominant on, if not limited to, one side or one limb (Ollier's disease)¹ or of a severe epiphysal disturbance in which the heads of the femurs are practically absent in most cases and there is marked kyphosis and dwarfism (Morquio's disease).² It seems likely that achondroplastic dwarfism is a related condition.

In addition to these types, which seem sufficiently well differentiated to have led various authors to designate them as specific diseases, a good many individual deformities have been reported in the literature, each having some characteristic which sets it slightly apart from all others. Among these are the ones reported by Lance,³ Valentin,⁴ Ellman,⁵ Campbell,⁶ Warkany and Mitchell,⁷ Deutschländer,⁸ Denks,⁹ Coward and Nemir,¹⁰ Siegert,¹¹ Ehrenfried,¹² Silfverskiöld,¹³ Dale,¹⁴ Turner,¹⁵ Jansen¹⁶ and Dwyer.¹⁷ The terminology is thus confused and conditions doubtless belonging in this complicated group of congenital osseous dystrophies have been described under such titles as familial osteochondrodystrophy, dyschondroplasia foetalis, chondrodysplasia, osseous dystrophy, atypical achondroplasia,

From the Children's Hospital.

Acknowledgment is made to Dr. Ralph DeGraff and Dr. John Barnes for interpretation of the roentgenograms and to Dr. E. C. Holscher of Duke Hospital for securing the data on case 4.

In many of the cases reported changes in the shape of the vertebral bodies have been noted. The bodies may be flattened (platyspondylisis), wedge shaped, oval

or otherwise irregular and deformed. Valentin particularly called attention to the vertebral changes, which he considered one of the essential features of the disease. My four patients all showed such changes, and in two cases the characteristic picture was revealed by roentgenograms of the spine long before clinical changes were manifest.

The cases here reported were of the type commonly referred to as Morquio's disease. This syndrome has been variously ascribed to a defect of calcium metabolism, a primary disorder to

Fig. 1 (case 1).—Note the short trunk and neck and the characteristic semi-crouching stance.

the nervous system, an endocrine disturbance and a primary hypermotility of the ligamentary apparatus; it has been designated as a forme fruste of achondroplasia of Parrot and as an osteochondropathy *sui generis*. At present there is fairly general agreement that it is a relatively rare variety of osteochondrodystrophy. Only about thirty typical cases have been reported since Morquio's description of the syndrome.

The story of the development of the deformities in the affected members of this family is the same in all cases. All were apparently normal at birth. At the age of 5 or 6 years the spinal changes had become sufficiently marked to be noticeable to the parents as a "round shoulder" posture. Thereafter the condition was inevitably slowly progressive until the characteristic deformity had occurred.

Of twenty persons in this family known to have inherited the defect, it has been possible to examine the four whose cases are reported. Examination, including roentgenograms, of six members of the family who were considered normal was made, and in these no bone defects were found.

CASE 1.—History.—J. L., a white boy aged 15, had appeared normal after a spontaneous birth, but as he began to grow his parents noticed that his body was not developing into the ordinary conformation. Gradually his shoulders seemed to be held higher, his neck to appear shorter and his chest to increase in size out of proportion to the rest of his body. In spite of the deformity he had always been well and active, walking and riding a bicycle until two weeks before admission to the hospital. At the age of 2 years he had measles followed by pneumonia, and the mother dated some apparent effort in breathing from this illness.

Two weeks before admission to the hospital he began to complain of pain in his back and of weakness. Several days later he collapsed on the floor because of pain, after which he was unable to get out of bed or even to lie comfortably.

Physical Examination.—The breathing was somewhat noisy because of mild asthmatic bronchitis. Otherwise no abnormalities were noted except the deformities of the body and the evident discomfort when voluntary movements, such as turning over in bed, were attempted. The patient was well below average height. The neck was very short. There were marked kyphosis and pigeon breast, with short trunk. There were moderate knock knee and flat foot and general muscular flabbiness. A psychologic examination showed the patient to be of average intelligence.

X-Ray Examination.—The vertebral bodies appeared flattened and broadened. The vertical dimensions were reduced about 30 per cent. Both superior and inferior borders were irregularly wavy as a result of unequally distributed disk pressure. The intervertebral disk spaces were narrowed, and in the middorsal region disk calcification was noted. Some squaring of the anterior margins of the vertebral bodies had occurred, and this was accompanied by the appearance of very early fringing. There was a moderate increase in the rounded dorsal kyphosis. The articular aspects of the ribs participated in the dysplasia, being flattened and broadened and showing a slight indentation in place of their normal articular tubercle. It was noted also that the angle between the neck and the shaft of the ribs was practically absent; anteriorly the ribs appeared slightly expanded at their costochondral junction and presented a ragged mixed

cystic and sclerotic appearance such as is seen in disturbances of cartilage transformation into bone. The anteroposterior diameter of the chest was relatively increased.

Repeated examinations of the urine gave entirely negative results. The hemoglobin content was 110 per cent, or 16 Gm. per hundred cubic centimeters. A blood count revealed 5,250,000 red cells and 6,800 white cells, with 80 per cent polymorphonuclears, 12 per cent lymphocytes and 4 per cent mononuclears. The sedimentation rate was 10 mm. and the blood calcium content was 8 mg. and the blood phosphorus content 4.76 mg. per hundred cubic centimeters.

Course.—Because of extreme pain in the back on any motion, particularly when the lower extremities were straightened out, the child was placed on a Bradford frame. Although several attempts were made in the course of the ensuing

Fig. 2 (case 1).—J. L. at the age of 17, photographed beside a normal boy of the same age.

year to get him up, it was always necessary to return him to the frame. At the end of twelve months it was possible for him to leave the frame and walk with crutches without pain. It is now two years since his admission to the hospital; his spine is rigid and free from pain and he walks without difficulty.

CASE 2.—History.—W. P., aged 7½ years, a first cousin of patient 1 and a brother of patient 3, had a normal birth and

developed normally, walking at 9 months and talking at 12 months. He had had measles, whooping cough and a moderate number of colds. Since the age of 5 years he had complained of pain in his back and legs but had been able to lead an average active life.

Physical Examination.—Except for enlarged tonsils and palpable cervical lymph nodes, the only abnormalities noted were the conformation of the back and the posture. The abdomen was protuberant, there was rather marked lordosis and there was slight scoliosis. The left shoulder was held high and forward and the right shoulder lower and back. The gait was rather stiff.

X-Ray Examination.—Study of films of the lumbodorsal area and pelvis revealed an unusual alteration in the shape of the vertebral bodies, which was most marked from the seventh dorsal to the first lumbar vertebra. The bodies in this area appeared nearly ovoid in the lateral projection, the peripheral structures on both the superior and the inferior aspects being undeveloped. This ovoid appearance in conjunction with the anterior vascular indentation resulted in a vertebral body which, seen laterally, resembled a sunfish. The superior dorsal and lower lumbar vertebral bodies showed similar less marked changes, and a general flattening and decrease in the height of the bodies were present throughout. The normal rounded dorsal kyphosis was slightly exaggerated. In the pelvis there was an increased density on both sides of the sacro-iliac joints. Some loss of joint space was apparent. Both acetabulums were slightly enlarged, the appearance giving the impression that weight bearing had caused a slow, mild compression of their superior aspects. The superior margin showed beginning spur formation, and mixed cystic and sclerotic changes were present in both the acetabulums and the femoral heads. The latter presented slight flattening with mixed condensation and rarefaction suggestive of an osteochondritic process.

CASE 3.—History.—J. P., aged 3½ years, a brother of patient 2 and a cousin of patient 1, began to walk at 9 months and talked at 15 months. There were no complaints, and the history was irrelevant.

Physical Examination.—The patient seemed normal except for moderate lordosis. But for the knowledge of the spinal defect of the brother and cousin, this mild lordosis might not have been noted.

X-Ray Examination.—Studies of the dorsal and lumbar sections of the spine and of the pelvis revealed in the middorsal segments changes which were suggestive of the process noted in case 2. The sixth and seventh segments showed the rounded anterior aspect with increased vascular indentation, whereas the immediately adjacent bodies above and below showed a failure of squaring, which gave them a more ovoid appearance in the lateral projection. This process was accompanied by a slight flattening and broadening of the bodies, the lateral dimensions increasing at the expense of the vertical. The acetabular roofs showed slight condensation.

CASE 4.—History and Examination.—J. B., the grandfather of patients 1, 2 and 3, had a history of kyphosis beginning in childhood and growing gradually more pronounced until early manhood. No change was noted thereafter except increasing rigidity of the back and hips in recent years. He had been able to lead

an ordinarily active life. Physical examination revealed the changes noted in figure 4.

X-Ray Examination.—Films of the skull revealed it to be of a dolichocephalic type with prognathic jaw. Rather marked pneumatization of the nasal accessory sinuses had occurred, the frontal sinuses extending well up into the diploe. A moderate increase in the venous channels was noted, particularly over the posterior part of the parietal region. The sella was of the flat ovoid type and showed no erosion of the clinoidal processes or floor. The teeth presented the flattened, eroded crowns seen in habitual tobacco chewers, and multiple periapical rarefactions were present. The cervical portions of the spine which were seen presented flattening of the bodies, narrowing of the disks and peripheral hypertrophic changes. The posterior articular facets showed no unusual involvement.

Lateral films of the dorsal and lumbar portions of the spine revealed flattening and broadening of the vertebral bodies with narrowing and calcification in the disk spaces. The subchondral bone plates showed sclerosis, while the spongy portions appeared osteoporotic and showed exaggerated linear striations. The normal rounded curves appeared exaggerated, and the entire spine was decreased in length.

A flat film of the pelvis and lumbar part of the spine revealed rather marked osteo-arthritis changes at both hip joints. The joint spaces were practically obliterated. Both the acetabulums and the femoral heads showed mixed cystic and sclerotic changes, with the latter predominating. The femoral necks were shortened, and the heads were flattened and deformed. A marked disproportion in development existed between the pelvis and thorax, the bony structures in the pelvis being about the size seen in a child of 12 or 14 years, whereas the thorax showed the development of a small adult; the lumbar part of the spine presented a dextroconvex curvature which, together with the previously noted flattening and decrease in vertical dimension of the bodies, permitted the lower ribs to come within 2 cm. of the crest of the ilia.

Films of the knees revealed evidence of mild chronic atrophy of the bones with flattening of the articular condyles of both femurs and tibias. On the right some hypertrophic changes were present, and sclerosis of the subchondral bone was noted in the lateral condyles of both tibia and femur. Calcification of the medial meniscus was present on this side, and on each side the soft tissues appeared somewhat atrophic.

A typical example of well marked osteochondrodys trophy of the Morquio's disease type (fig. 1) is characterized by changes in bodily conformation resulting in the main from the shortening of the spinal column and of the necks of the femurs. The patient is moderately dwarfed, with pigeon breast, kyphosis and compensatory lordosis. Because the narrowing of the vertebral bodies includes those of the cervical region, the neck is so short as to seem absent, and the head,

Fig. 3 (case 2).—Note the beginning rounding of the upper back and lordosis.

Fig. 4 (case 4).—The end stage of the deformities with markedly shortened spinal column and barrel chest.

although of normal size, appears large. Changes in the pelvic bones and the upper ends of the femur cause the patient to stand in a semicrouching position. The joints are restricted in motion, and the gait is stiff. Other than the skeletal defects there are no organic changes, and the mentality is normal.

Fig. 5 (case 2).—Early changes in the vertebrae. Note the rounding and pointing of the anterior aspect of the vertebral bodies.

who has a sex-linked recessive trait to a normal woman yields all normal offspring. The sons will be completely normal but the daughters will be carriers, capable of transmitting the disease to their sons. A woman who is a carrier of a sex-linked recessive disease who marries a normal man will produce all normal daughters,

Fig. 6 (case 4).—Late changes in the pelvis, with complete fusion of both hip joints.

The mode of heredity of the defect in this family as revealed by the pedigree is of peculiar interest because of the large number of affected persons. It appears to be a characteristic that is carried by the sex chromosome. It is known that some traits in addition to sex are regularly carried by the sex chromosome, and the traits whose genes are shown to be located in the sex chromosome have proved always to be recessive.

With this type of heredity the mating of a normal man and a carrier woman yields all normal offspring. The sons will be completely normal but the daughters will be carriers, capable of transmitting the disease to their sons. A woman who is a carrier of a sex-linked recessive disease who marries a normal man will produce all normal daughters, while approximately one half of her sons will be affected and one half normal. The only way in which it is possible for a woman to show a sex-linked recessive character is for her father to be affected and her mother either affected or a carrier. With such rare diseases as osteochondrodystrophy, this combination is highly unlikely to occur except when related persons

marry. In this family the indications are that one is dealing with this type of sex-limited inheritance carried through the female. It will be noted that the theoretical distribution of affected and unaffected persons is rather closely followed, as shown in figure 7. Only one affected male had offspring, but, fortunately for the purposes of this study, they were numerous enough practically to exclude chance as a factor to explain the complete absence of the defect in his children.

On the other hand, Shelling¹⁸ stated that the heredity of osteochondrodystrophy is probably determined by a dominant mendelian factor. However, in studying the pedigrees of families with various defects of bone and cartilage, Madge Macklin¹⁹ found that achondroplasia was inherited as a dominant characteristic in twelve families and as a recessive characteristic in five, acrocephaly as a recessive character in almost all cases, cranioleiodysostosis as a dominant characteristic in twenty-two families and as a recessive characteristic in two; craniofacial dysostosis as a dominant characteristic in three families and as a recessive characteristic in one; and exostoses as a dominant characteristic in most instances. It therefore seems likely that with osteochondrodystrophy also the type of inheritance may not be the same in all affected families.

Patients 1 and 4 suffered from a severe disabling type of arthritis. At the present time patient 1 is able to get around again and to ride a bicycle after having been practically bedridden for one year as the result of a rapidly progressive form of this disease. The occurrence of arthritis secondary to defective development of the cartilage in articulating surfaces would seem a logical sequence, but this association has not been noted frequently in reported cases. It is interesting to note also that both the mother of patient 1 and her sister, the mother of patient 2, have marked arthritic processes

Fig. 7.—Pedigree; the hollow squares indicate normal males; the solid squares affected males and the circles females.

in the hips and ankles, although of course there are no evidences in these persons of osteochondrodystrophic changes.

No form of therapy has proved in the least effective for osteochondrodystrophy. Nothing would seem likely to produce results except birth control measures on the part of those capable of transmitting the defect. One can but subscribe, with Dr. Macklin, to the creed of the Persian sage:

*Better, ah better cancel from the scroll
Of Universe one luckless human soul
Than drop by drop enlarge the flood that rolls
Hoarser than anguish as the ages roll.*

Robert Jones.—Possibly in the years to come the constant insistence by Robert Jones of the functional necessity of alignment, rather than mere end-to-end apposition, of fractured bones, will stand out as his most original and scientific contribution to his art. Robert Jones was also the first surgeon successfully to transplant the flexor muscles of the forearm into the extensors in a case of irreparable injury to the musculospiral nerve. Moreover, his untiring advocacy of tendon transplantation, bone grafting, and other conservative and physiologically restorative procedures, has led to the general adoption of such methods, the beauty as well as the usefulness of which so greatly appealed to him.—Power, Sir D'Arcy: British Masters of Medicine, Baltimore, William Wood & Co., 1936.

Clinical Notes, Suggestions and New Instruments

PLASTIC REPAIR WITH CARILAGOPERIOSTEAL BRIDGE IN DROOPING (OR DOG) EAR

JAMES P. RIGG, M.D., AND RICHARD WALDAPFEL, M.D.
GRAND JUNCTION, COLO.

There are many operations offered for plastic repair of the protruding ear, also called lop ear, bat ear and outstanding ear (Ruttin, Alexander, Leidler, Joseph and others). Only recently MacCollum¹ described three methods of operative choice in these cases. He also gave a detailed account of the developmental anatomy.

However, much less is written about another anomaly, the so-called drooping ear. In this malformation the superior bow of the helix and the crus helices are rolled downward away from the head, covering more or less the scaphoid fossa. As in the protruding ear, with which it is often combined, the antihelix is very small or not present.

Every operation should be so devised as to place the malformed part in its proper position, with utilization of such reconstructive measures as are necessary to do this. In the drooping ear it is necessary to lift the ear to its normal position and to reconstruct the antihelix and scaphoid fossa. Concerning these the following must be taken into consideration:

It is apparent that to keep the ear in the upright position requires much more anchorage than is required in merely attaching the ear behind as in the protruding ear. In other

Fig. 1.—Appearance of patient before operation.

words, some method must be applied to hold the ear in position so that it will not droop again. Merely attaching it above on the skin is not sufficient because of the possible subsequent sagging of the superior bow of the helix.

In correcting protruding ears, the usual procedure is to excise either the skin from behind the ear or the cartilage from the ear, or part of each. In the drooping ear we didn't consider this sufficient. We have used and modified in a suitable case a method which Demel, a Viennese surgeon, has designed for the protruding ear.

A man aged 20 (fig. 1) showed maldevelopment of both ears. The right ear was a drooping ear and the left ear a flat, slightly macrotic ear with missing cartilage in the helix. He wanted to have only the right ear repaired, because it was the most conspicuous and prevented him, as he stated, from getting a job.

The principle of the operation is that the cartilage is only partially excised, the main portion being preserved, dislocated toward the periosteum of the temporal bone and fixed under it, so that the cartilage helps to keep the auricle in the desired new position.

The operative technic is as follows (fig. 2): The line of infiltration shown in sketch 1 for local anesthesia (1 per cent procaine hydrochloride with epinephrine) gives perfect anesthesia in these cases. Sketch 2 shows the line of incision and excision above and behind the ear; the skin between the incision lines *ABC* and *ADC* is excised, the midportion *AC* being the line of insertion of the auricle. Half of this excised

area lies on the posterior surface of the auricle and the other half on the mastoid region superior to it. After complete exposure of the cartilage that portion which is to be preserved for insertion of the cartilaginous subperiosteal bridge is circumscribed by a sharp incision (the portion is made large enough, for it can always be modified) and separated from the underlying skin, which is the anterior surface of the auricle (sketch 3, black area). The periosteum of the squama is exposed, blunt dissection being made first through the temporal muscle and then two incisions being made in the periosteum of the mastoid region, parallel to the line of insertion of the auricle.

Fig. 2.—Stages of operation.

These parallel lines are from 4 to 6 mm. apart; the periosteum is elevated between them and the periosteal portion of the bridge formed. The separated cartilage of the auricle, which is the cartilaginous portion of the bridge, is turned backward, as shown in sketch 4, pushed under the proximal incision of the periosteal bridge and pulled out through the distal incision. The cartilage is temporarily held in place with forceps until the desired position is obtained; then it is sutured to the periosteum and fascia with 00 plain catgut; usually three sutures are sufficient, thus fixing the cartilagoperiosteal bridge. By this procedure the auricle is elevated to its desired position and a new antihelix is formed at the line where the cartilage is deflected backward on itself. The subcutaneous tissue is firmly approximated over

Fig. 3.—Appearance of patient after operation.

the bridge and sutured. The lines of incision are brought together (sketch 5); it may be necessary to excise a millimeter or more of the skin along one or the other border before the edges are sutured exactly. Sketch 6 shows the ear after the operation has been completed. A complicated dressing for the ear is not necessary. The typical or usual dressing used after an operation on the ear is applied.

A little trick which has proved so satisfactory in all our dressings is to place a piece of bandage from 6 to 10 inches

From the Eye, Ear, Nose and Throat Clinic.
Read before the Colorado Oto-Laryngological Society Nov. 5, 1938.
1. MacCollum, D. W.: The Lop Ear, *J. A. M. A.* 110:1427 (April 30) 1938.

long vertically over the eye on the side of the operation down to the mouth. The bandage is then started or held over the ear that has been operated on. It proceeds over the forehead and around the opposite side. Keeping always above the opposite ear and under the occipital protuberance, one makes successive tours of the head, fixing the upper, lower and central portions of the gauze over the side operated on and tying the original 6 inch strip as tightly as necessary to hold it firmly on and around the ear, forming a sort of self-retaining cap for the ear.

The described method has the following advantages:

1. It fixes the auricle firmly in the new position and prevents it from springing back into its former position.
2. It allows a new antihelix to be formed at the point where it is desired during the operation.
3. It controls the angle of fixation between the auricle and the temporal portion of the head by allowing the operator to pull on the cartilaginous flap during the operation. The scaphoid fossa is automatically pushed forward.

Figure 3 shows the results of this procedure. We have found it most efficacious in our hands and recommend it as a method to be borne in mind in this type of plastic repair of the malformed ear.

AN UNUSUAL CASE OF INTRA-GROUP AGGLUTINATION

PHILIP LEVINE, M.D., NEWARK, N. J., AND RUFUS E. STETSON, M.D.,
NEW YORK

This report deals with a rare property in the blood of a patient whose serum showed an iso-agglutinin of moderate activity, which agglutinated about 80 per cent of the bloods of her own group. In view of the fact that this agglutinin tended to disappear after an interval of several months and the fact that this agglutinin gave an equally strong reaction at 37 and 20 C., it would seem to resemble agglutinins resulting from iso-immunization following repeated transfusions. This phenomenon is readily reproduced in some species (cattle, chickens, rabbits), by several repeated transfusions, but in the case of man only two clearcut instances of such iso-immunization to cellular elements are described in the literature.¹ The case to be described differs from these in that the immune iso-agglutinin must have been stimulated by a factor other than repeated transfusion. The nature of this factor becomes evident from a summary of the case history.

REPORT OF CASE

M. S., a woman aged 25, a secundipara, was registered in the antepartum clinic of Bellevue Hospital July 12, 1937, at which time she showed some pretibial edema and a blood pressure of 130 systolic, 90 diastolic. (The expected date of delivery was in the last week of October.) Two weeks later the blood pressure was 154 systolic, 106 diastolic, and there was a faint trace of albumin in the urine. Hospitalization and rest in bed resulted in subsidence of all symptoms. The fetal heart sounds were not heard, but there were no x-ray signs of fetal death.

Labor pains and vaginal bleeding started on September 8 (the thirty-third week of the gestation), and at midnight September 9 the patient was admitted to the hospital, at which time labor pains lasting one minute occurred every five minutes. There was considerable bleeding before the membranes were ruptured, and a macerated stillborn fetus weighing only 1 pound 5 ounces (595 Gm.) was delivered. After the placenta was expelled, bleeding was finally controlled and the patient (group O) was given her first transfusion of 500 cc. of whole blood from her husband (group O). Ten minutes after she received the blood a chill developed and she complained of

pains in her legs and head. About twelve hours later a piece of membrane was passed and this was followed by more bleeding. At 4 p. m. a second transfusion of 750 cc. of whole blood was given, apparently without any reactions. In view of the renewed bleeding, hysterectomy was performed, followed by a third transfusion of 800 cc. of whole blood with no reaction.

Nineteen hours after the first transfusion and eight hours after the hysterectomy the patient voided 8 ounces (240 cc.) of bloody and dusky urine. At this time tests done with a more delicate technic revealed that, although the patient and her husband—the first donor whose blood caused a reaction—were in group O, the patient's serum nevertheless agglutinated distinctly her husband's cells and, indeed, the cells of most group O donors. Subsequently the patient received six more uneventful transfusions from compatible professional donors very carefully selected by the Blood Transfusion Betterment Association.

Subsequent intensive treatment—diathermy over the kidneys, forced fluids by vein, rectum and mouth, the repeated transfusions mentioned and high hot colonic irrigations—resulted in gradual recovery of kidney function.

COMMENT

The blood was referred to us during the patient's convalescence, October 9, a month after the hysterectomy. Tests previously performed at the Donor Bureau of the Blood Transfusion Betterment Association showed that only eight of fifty group O donors did not react with the patient's serum and hence were compatible. In our series of fifty-four bloods of group O, thirteen failed to react with the patient's serum. Thus, of a total of 104 group O bloods twenty-one were compatible.

It could be readily shown that these reactions differ from those due to so-called atypical agglutinins occasionally found in the serums of normal persons. The former reactions were just as active at 37 as at 20 C., while reactions of the latter variety as a rule do not occur at 37 C. or else are considerably diminished. In other words, identical results were obtained when tests with serums of the patient were kept either at 20 or at 37 C. or were read after centrifuging and resuspending the sedimented cells.

The reactions were found to be independent of the M, N or P blood factors. Owing to the lack of suitable quantities of the blood, it was not possible to perform absorption experiments in order to supply data on the incidence of the reactions in bloods of groups A, B and AB.

Another specimen drawn two months later, December 3, still exhibited the agglutinin, which however gave far weaker reactions. Here again the reactions at 37 C. were just as intense as those at room temperature or lower. It was not possible to examine the serum of this patient until a year later, when all traces of reactions had disappeared.

In several respects this iso-agglutinin, as already mentioned, resembles the iso-agglutinins described by Landsteiner, Levine and Janes and that of Neter, namely (1) reactions within the same group equally active at room temperature and at 37 C. and (2) the temporary character of the agglutinin. In both of these cases the agglutinin was not demonstrable until an interval of several weeks had elapsed following repeated transfusions. In the present case, however, it is evident that the unusual iso-agglutinin must have been present at the time the patient was given her first transfusion with the blood of her husband, which subsequently was shown to be sensitive. Furthermore, this first transfusion was not uneventful in view of the resulting chills, pains in the legs and intense headache.

It is well established that in instances of iso-immunization in animals the iso-agglutinin serves as a reagent to detect dominant hereditary blood factors in the red blood cells and presumably also in the tissue cells. In view of the fact that this patient harbored a dead fetus for a period of several months, one may assume that the products of the disintegrating fetus were responsible not only for the toxic symptoms of the patient but also for the iso-immunization. Presumably the immunizing property in the blood and/or tissues of the fetus must have been inherited from the father. Since this dominant property was not present in the mother, specific immunization conceivably could occur.

From the Department of Laboratories, Newark Beth Israel Hospital, Newark, N. J., and the Blood Transfusion Betterment Association of New York City.

Dr. William E. Studdiford, director, and Dr. John S. Labate, resident, of the Obstetrical and Gynecological Service at Bellevue Hospital, gave the authors permission to study this case.

1. Landsteiner, Karl; Levine, Philip, and Janes, M. L.: *Proc. Soc. Exper. Biol. & Med.* 25: 672 (May) 1928. Neter, Erwin: *J. Immunol.* 30: 255 (March) 1936.

No data are available as to the relationship to one another of the immune iso-agglutinin in the two previously reported cases and in the present case. Judging from the frequency of positive and negative reactions, it is evident that the iso-agglutinin in this case is distinct from the other two; i. e., 20 per cent nonreacting bloods in contrast with 75 per cent in the case of Neter and 60 per cent in that of Landsteiner, Levine and Janes.

Agglutinins of this sort can rarely be investigated thoroughly because of their tendency to diminish in activity and eventually to disappear. Consequently attempts were made to produce a hetero-immune agglutinin of identical or similar specificity by repeated injections of sensitive blood into a series of rabbits. These experiments met with failure, since suitable absorption tests with such serums failed to reveal the presence of the desired agglutinin.

201 Lyons Avenue, Newark—48 East Sixty-Fourth Street, New York.

Council on Foods

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT.
FRANKLIN C. BING, Secretary.

KNOX GELATINE OMITTED FROM THE LIST OF ACCEPTED FOODS

It is one of the rules of the Council¹ that firms having accepted products shall submit suitable evidence for new claims before use is made of them in advertising. The Charles B. Knox Gelatine Company, Inc., Johnstown, N. Y., manufacturers of Knox Plain Sparkling Gelatine, a product which has been accepted² since 1931, has been aware of this requirement. Recently certain claims have been widely promulgated before the Council had an opportunity to review the evidence on which they were based. These new claims, and others which have not been so widely advertised, are discussed in the present report.

In an earlier report³ on "The Nutritional Significance of Gelatin," there were summarized the following claims that can be recognized for gelatin:

"In view of the available evidence the Council believes that gelatin properly made is a wholesome food, that it has special usefulness when one desires to add variety to the diet by incorporating gelatin in nutritious soups or pleasant desserts which appeal to the appetite of many persons, and that for these reasons gelatin is often a useful food for inclusion in the diet of healthy persons or of sick or convalescent patients. Gelatin appears to be well tolerated. The claim that gelatin is an aid in the digestion of milk, however, is in the opinion of the Council not established. The claim that gelatin is of value as a source of aminoacetic acid in the treatment of some of the myopathies cannot be recognized; in the light of present evidence, gelatin has no special significance as a source of amino acids in the diet. Indeed, it is notoriously deficient in certain essential amino acids."

Recent publications bearing on the properties of gelatin have not changed the status of these allowable claims.

GELATIN AND FATIGUE AND ENDURANCE

Early in 1939 there appeared a report⁴ by Profs. G. B. Ray and J. R. Johnson and Miss M. M. Taylor on the "Effect of Gelatine on Muscular Fatigue." These authors at Long Island College of Medicine selected six men and four women who were trained on the ergometer "until the maximal output of work before fatigue set in was as constant as could be expected under the experimental conditions." The subjects were then given 60 Gm. of gelatin daily (three of the women received 45 Gm. and one 67.5 Gm., but because negative results were obtained with women, only the experiments on men need be considered). Knox Plain Sparkling Gelatine was taken by mixing 30 Gm. of the dry material in 8 ounces of chilled orange and lemon juice and drinking the mixture before the gelatin swelled appreciably. With the male subjects there was noted a marked

increase in the total watt output, which increased gradually from day to day until apparent maximum effects were produced. The gelatin, but not the fruit juices, was then discontinued. Thereafter it was found that the total watt output gradually diminished and approached the level observed prior to the gelatin feeding. The authors concluded that men who are given adequate amounts of gelatin are invariably able to increase the amount of work produced before fatigue sets in. The results varied from 37 per cent to 240 per cent above the training level, but in the greater number of subjects the increase is said to have been more than double. The authors suggested that the action of gelatin which they observed was concerned with the creatinogenic action of its amino acids, especially aminoacetic acid, which makes up about one fourth of the weight of this protein.

The experiments of Ray and his associates cannot be considered as conclusive. They represent uncontrolled observations because no comparisons were made of the effect of feeding other proteins or other substances. The authors seem inclined to interpret their results in terms of the component amino acids of gelatin, but they did not report any observations on the effects of feeding aminoacetic acid itself. It should be obvious that observations such as those reported on six men cannot be applied to all men until experimental confirmation is available from other laboratories. There might be some basis for believing that the administration of aminoacetic acid⁵ or of gelatin may result in a gain in strength or endurance of persons with asthenia of various types, but young healthy men would not be expected to exhibit such marked effects as those reported. Perhaps the chief point of criticism about the work performed in the Long Island College of Medicine is that the feeling of fatigue was the criterion for stopping work each day. It is well known that the mental factor in fatigue is enormous, and some method of controlling this factor could well have been included in the planning of the experiments. On the basis of available evidence the Council cannot recognize the claim that gelatin lessens or postpones fatigue.

In its advertising the firm has claimed that the taking of rather large quantities of Knox Gelatine increases muscular endurance, postpones fatigue, causes no disturbance in digestion and does not interfere with normal appetite. (For a true test, the firm stipulates that the gelatin should be continued daily for at least a month.) The firm was asked why these claims for Knox Gelatine were being used when they had not been accepted by the Council. The general manager of the firm replied by telegram in part as follows:

"News stories on gelatin New York papers broke unexpectedly and was forced to run one piece copy locally to protect position against other gelatins claiming responsibility for work done on our grants."

In a further communication, the firm has written:

"Even though this new use of Knox Gelatine is not directed to persons under medical care but is strictly a lay proposition, we would have preferred to withhold advertising it to the laity [sic] until the Council had passed on it."

"As brought out in our previous letter, competitive brands that did not have the Council's seal, and with no regard for ethics—business or otherwise—started to advertise their products for this use which forced us to either adhere strictly to the Council's rules or let competitors reap the benefit of the research that we instigated and paid for."

The actions of the Knox Gelatine Company in advertising its product with unaccepted and misleading claims may be justified by the business ethics of the concern; but in the opinion of the Council that is no justification for the spreading of unestablished propaganda to the public.

GELATIN IN THE DIET OF THE DIABETIC PERSON

The Knox Gelatine Company has published a booklet entitled "The Diabetic Diet and Knox Sparkling Gelatine." Although it is a requirement of the Council that all advertising for accepted products must be acceptable to the Council, the firm

1. Rules and Regulations of the Council on Foods of the American Medical Association, January 1939, p. 13. This publication, which is reprinted frequently, is available for the asking from the Secretary of the Council, 535 North Dearborn Street, Chicago.

2. Committee on Foods, J. A. M. A. 96: 861 (March 14) 1931.

3. The Nutritional Significance of Gelatin, Report of the Council on Foods, J. A. M. A. 107: 2132 (Dec. 26) 1936.

4. Ray, G. B.; Johnson, J. R., and Taylor, M. M.: Effect of Gelatine on Muscular Fatigue, Proc. Soc. Exper. Biol. & Med. 40: 157 (Feb.) 1939.

5. It perhaps should be mentioned that the physiologists at the Long Island College of Medicine misquoted comments of Dr. Russell M. Wilder which were made in discussing a series of papers on the treatment of the myopathies. These were published in the Proceedings of the Staff Meetings of the Mayo Clinic, Oct. 3, 1934. Ray and his collaborators write: "Wilder believed his ability to play tennis increased after two weeks on a glycine diet." What Wilder and his son did was to determine the creatine content of urine after a vigorous game of tennis. Six-hour specimens of urine collected immediately after this exercise contained 21 mg. of creatine for both persons. Two weeks then intervened, during the second week each person took 6 Gm. of aminoacetic acid daily and then again played a vigorous game of tennis. Six-hour specimens of urine after this bout of exercise contained 13 and 4 mg. This is quite different from stating that the administration of aminoacetic acid increases one's "ability to play tennis."

never submitted the booklet in current use until after it had been published and the Council office had requested a copy. Knox Gelatine is referred to in this booklet as "the ideal food for the diabetic," and as a preparation which "can and should be substituted" for most protein foods. There is illustrated in this booklet a diet description by "John Doe, M.D.," which contains the direction "Use Knox Gelatine freely." The booklet includes a foreword by the firm, a page entitled "To the Reader," brief descriptions of the "Principles of the Diabetic Diet," a discussion of the caloric requirements and other general questions. There are pages devoted to Knox Gelatine in the diabetic diet, tables of the composition of foods, a list of forbidden foods, and seven daily diabetic menus "compiled by a trained dietician" which provide a scheme for diets providing from 1,000 to 2,000 calories daily. The booklet contains also a considerable number of recipes for foods, for many of which Knox Gelatine is an ingredient.

This booklet, which could be a useful educational item, is objectionable because much of the information that it provides is outmoded or incorrect. The dietary recommendations are not in agreement with current views of the foremost writers and authorities on the subject. The menus are for the high fat, low carbohydrate type of diet. Although the booklet quotes the recognized principles that the diet for the diabetic must provide foods whose caloric value meets the daily requirements, and protein to equal that of the normal diet, the calories and protein of the menus are unusually low. Can the daily menu which provides 1,000 calories from 38 Gm. of protein, 75 Gm. of fat and 50 Gm. of carbohydrate be intended for children? Or is it intended for adults who need to lose weight? Why is the protein so low? Even the menus providing 1,600 calories, which might be a satisfactory caloric intake for some women, offer only 45 Gm. of protein. This is rather low, particularly when one realizes that some of this protein is in the form of gelatin, a notoriously deficient protein.

A detailed criticism of this booklet might require more space than the booklet itself. That a commercial firm should distribute advertising in the guise of brochures or textbooks on the management of diabetes and other diseases may be only a sign of the times, but it is an insult to the intelligence of physicians to circulate material which is poorly prepared or out of date. Yet without submitting this objectionable booklet to the Council the firm published advertisements in newspapers inviting the readers to write for a copy, and for a free sample of Knox Gelatine.

GELATIN AND PEPTIC ULCER

The Knox Gelatine Company recently requested the Council to consider the claim that gelatin is useful for persons with peptic ulcer. In support of this claim there was offered a report⁶ by Drs. Charles Windwer and Milton J. Matzner of the Jewish Hospital of Brooklyn. These authors administered a high protein diet, consisting of a mixed diet with hourly feedings of gelatin between meals, to forty patients with peptic ulcer. Seven doses, each of 8 Gm. of gelatin dissolved in a small amount of water, were administered daily. It was reported that symptomatic relief was obtained in 90 per cent of the patients studied. Although recognizing that this method is not a specific, the authors assert that gelatin has a definite place in the management of peptic ulcer, especially when patients do not respond to drug therapy.

It is well known that the person with peptic ulcer has periods of relapse and of relative freedom from symptoms. The observations in the present report are wholly subjective. Further study is definitely indicated before the claim can be considered established. Certainly there is no justification for suggesting that persons with peptic ulcer obtain relief by feeding themselves gelatin between meals, as the firm has done in newspaper advertisements. The following excerpt is an example of objectionable advertising:

"GASTRIC ULCERS?"

"With gastric ulcers, you must avoid irritating the inflamed area and, at the same time, get enough nourishment to keep up your strength. "Between meals (hourly or at least every two hours), take half an envelope of Knox Gelatine in a cup of fruit juice, milk or water. The gelatine helps lessen pain. Because it's a food, it helps to build up strength and resistance."

6. Windwer, Charles, and Matzner, M. J.: Peptic Ulcer—The Effect of High Protein Diet on the Behavior of the Disease, *Am. J. Digest. Dis. & Nutrition* 5: 743 (Jan.) 1939.

GELATIN IN THE FEEDING OF INFANTS

The Council in 1936 refused to recognize the claim that the addition of gelatin to milk is particularly advantageous in the feeding of infants. The Knox Gelatine Company in April 1939 asked for acceptance of the claim that "gelatinized" milk is better digested and utilized, based on old and new experiments. The firm refers to some experiments by Riggs and Beatty,⁷ who found that the addition of 2 per cent gelatin to milk brings about a reduction of the curd tension to approximately one half. Attention was also directed to a paper by Ruth E. L. Berggren⁸ on "The Effect of Gelatin on the Curd Tension of Milk." Her data show a maximal decrease of 48 per cent in curd tension, obtained with the addition of 4 per cent gelatin of high viscosity. One per cent gelatin of low viscosity produced a reduction of only 6 per cent in curd tension. In her conclusion it was stated: "The addition of gelatin (Knox) to milk caused a marked fall in the curd tension. In most cases, 2 per cent of gelatin added to milks of curd tension up to about 50 Gm. converted them to soft curd milks." There are two errors in these statements. First of all, the decrease in curd tension is not necessarily marked. Secondly, if milk with a curd tension of 50 Gm. has the curd tension diminished even 50 per cent, it is a "soft curd milk" only if one defines a soft curd milk as one having a curd tension of 30 Gm. or less.

It may be noted that neither of these reports offers any new evidence in support of the claim that "gelatinized" milk is better digested and utilized, a claim which the Council concluded was not supported by adequate evidence in 1936.

In regard to the claim that the addition of gelatin causes a reduction in the curd tension of the milk, there is evidence already cited and from other sources. For example, Kugelmass⁹ has reported that gelatin causes a considerable reduction in the curd tension of milk. In the accompanying table are provided illustrative values of the curd tension, of samples of milk examined by the Secretary, as measured with a standard knife, pepsin and hydrochloric acid being used as a coagulant:

Effect of Gelatin on the Curd Tension of Milk

	Curd Tension in Grams		
	Milk I	Milk II	Milk III
1. Pasteurized milk	30	54	46
2. Boiled (5 min.) milk	18	15	14
3. Milk and gelatin	25*	18	25

* 1.5 per cent Knox Gelatine; in the other experiments, 3 per cent Knox Gelatine.

It is evident from these data that there is a reduction of curd tension when gelatin is added to milk, but there is a greater decrease in the curd tension when milk is boiled. The Council already has gone on record as stating that all milk used for the feeding of infants should be boiled. There is, therefore, no point to the claim made for adding gelatin to milk. For older persons who do not use boiled milk, there may be some justification to the claim, but "gelatinized" milk is promoted for the purpose of infant feeding.

The claim also has been advanced that the feeding to infants of "gelatinized" milk reduces the incidence of constipation, minor gastrointestinal upsets and upper respiratory infections. These claims are based on two reports by Dr. C. Loring Joslin, professor of pediatrics at the University of Maryland School of Medicine and College of Physicians and Surgeons. The first report¹⁰ was published in January 1937. At that time the Council offered the firm, on request, a number of comments regarding the paper. These may be summarized as follows:

The claim is made that the addition of gelatin to cow's milk makes the milk more digestible for the average infant as evidenced by (a) the reduction of vomiting and (b) constipation, and (c) the production of a

9. Kugelmass, I. N.: Milk Curd—Its Mechanism and Modification, *Arch. Dis. Child.* 12: 25 (Feb.) 1937.

10. Joslin, C. L.: Some Clinical Observations on Feeding Infants Whole Milk, Gelatinized Milk and Acidified Milk: A Preliminary Report, *Arch. Pediat.* 54: 20 (Jan.) 1937.

better rate of gain. In the opinion of the Council, even though it is possible that gelatin is useful in vomiting, the data submitted are scarcely acceptable as evidence. Supporting data and discussion are necessary. For example, vomiting may have as its cause an infection of the upper respiratory tract. Vomiting from this cause alone will cease on recovery from the infection regardless of whether gelatin is added. Vomiting may result from swallowing of air incident to underfeeding. Such vomiting will tend to cease when sufficient food is given, whether or not it contains gelatin.

The Council questions whether constipation has any relationship to digestibility. The indigestible part of bran aids in the relief of constipation. Constipation may be caused by underfeeding, in which case any good formula will relieve it. Again a supporting discussion with data is necessary.

The point relative to the production of a better rate of gain requires a discussion of calories which is lacking. Apparently the control formulas had less energy value, the difference being in the amount of gelatin added to the experimental formulas. This isn't much, but it is from 30 to 70 calories a day, which is something. In the report of Elerich, Boyd and Neff, the energy values were kept approximately the same, and no differences were observed in the weight gain.

Dr. Joslin concludes that the addition of gelatin to milk protects against diarrhea. No evidence is presented that the figures in the table have any significance. In the cow's milk group were twenty-one babies with infection and fourteen with diarrhea. In the gelatin group were nine cases of infection and eight of diarrhea. Parenteral infection is one of the most frequent causes of diarrhea at the present time. These data without appropriate supporting discussion are far from convincing, in the opinion of the Council.

Attention is called by the investigator to the lower incidence of upper respiratory infections in the gelatin-milk group A. The claim that gelatin milk protects against pneumonia, whooping cough, chicken-pox and measles would be no more ridiculous than a claim based on this point brought to attention by Dr. Joslin.

The Council feels that the entire report shows a lack of critical observation and analysis. Only favorable portions are quoted from the literature.

In January 1939 a new report of "Further Clinical Observations on Feeding Infants Whole Milk, Gelatinized Milk and Acidified Milk" was published by Dr. Joslin.¹¹ One hundred and fifty infants were observed, and these were divided into three groups of fifty infants each. The first group received cow's milk; the second, milk to which gelatin had been added (the gelatin was Knox's brand), and the third group was fed acidified evaporated milk. During the period of observation of six months the infants fed cow's milk showed respiratory infections in nineteen instances and diarrhea in seven. Those fed acidified milk showed respiratory infections in twelve instances and diarrhea in nine. Of those fed "gelatinized" milk six had respiratory infections and three had diarrhea. There were five infants with diarrhea in the group fed cow's milk, three in those fed "gelatinized" milk and four in the group fed acidified milk. Other items also were listed, such as the gain in weight, incidence of vomiting, poor appetite and the like. In the summary the author stated that upper respiratory infections occurred less frequently in the group of infants fed a low curd tension milk produced by the addition of gelatin to the milk. He also concluded that the feeding of "gelatinized" milk may be helpful in cases of vomiting, diarrhea and constipation as compared to the feeding of cow's milk. In the opinion of the Council, none of these conclusions is entirely justified by the evidence.

SUMMARY

After reviewing more recent available evidence the Council reaffirms its previous decision about the allowable claims for gelatin. The claim that the eating of gelatin increases endurance or diminishes fatigue in normal persons is not acceptable. The supposed value of gelatin as a high protein food in the diet of diabetic patients cannot be recognized, although gelatin may be included advantageously in the diet of the diabetic patient. The claim that gelatin is of therapeutic value in the management of peptic ulcer is not considered to be established. Although the addition of gelatin to milk does lower the curd tension, the claim cannot be recognized that the addition of gelatin to milk intended for infant feeding is particularly desirable, for the reasons stated in the foregoing report. No claims can be recognized for the usefulness of gelatin in the prevention of vomiting, diarrhea, constipation and infection in infants on the basis of evidence presented.

Regardless of whether any one or all of the claims made by the Charles B. Knox Gelatine Company, Inc., Johnstown, N. Y., may later prove to be right or wrong, the company,

in making such claims without first submitting them to the Council, has violated obligations regarding the use of the seal of the Council. For this reason, by vote of the Council, the gelatin products of this firm have been removed from the list of accepted foods.

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COUNCIL ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION AND WILL BE LISTED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED.

FRANKLIN C. BING, Secretary.

- (1) BRUCE'S JUICES BRAND GRAPEFRUIT JUICE, UNSWEETENED
- (2) BRUCE'S JUICES BRAND GRAPEFRUIT JUICE, SUGAR ADDED
- (3) BRUCE'S JUICES BRAND ORANGE AND GRAPEFRUIT JUICE, SUGAR ADDED

Manufacturer.—Bruce's Juices, Inc., Tampa, Fla.

- Description.—(1) Canned, unsweetened Florida grapefruit juice.
(2) Canned Florida grapefruit juice containing added sugar.
(3) Canned mixture of Florida orange and grapefruit juice containing added sugar.

Manufacture.—(1) and (2) Sound, tree-ripened grapefruit are washed and mechanically halved and the juice is extracted by reamers operated by hand or mechanically. The juice is strained and sugar is added if a sweetened juice is being prepared. The juice is deaerated, flash pasteurized and immediately filled into cans, which are sealed and cooled. The juice is kept under vacuum throughout the process and only stainless steel equipment is used. The empty cans are fed through a live steam bath before being introduced into the filling machine.

(3) Formula proportions of Bruce's Juices Brand Orange Juice and Bruce's Juices Brand Grapefruit Juice Unsweetened are mixed, a small amount of sugar is added and the mixture is canned as described for Bruce's Juices Brand Grapefruit Juice, Unsweetened.

Analyses (submitted by manufacturer).—

	(1)	(2)	(3)
Moisture	89.0	83.7	84.0
Total solids	11.0	16.3	16.0
Ash	0.3	0.3	0.3
Fat (ether extract)	0.1	0.1	0.1

Titratable acidity as anhydrous citric acid	1.6	1.5	1.1
Vitamin C (titration)	43.7 mg. per 100 cc.	46.3 mg. per 100 cc.	59 mg. per 100 cc.
Vitamin C (titration) performed by Dr. E. M. Bailey of the Connecticut Agricultural Experiment Station at the request of the Council	35.2 mg. per 100 cc.	36.0 mg. per 100 cc.	44.2 mg. per 100 cc.

- Calories.—(1) 0.37 per gram; 11 per ounce.
(2) 0.58 per gram; 15 per ounce.
(3) 0.56 per gram; 17 per ounce.

CELLU BRAND PEAR JUICE

Distributor.—Chicago Dietetic Supply House, Inc., Chicago.

Description.—Canned pear juice packed without added sugar.

Manufacture.—Fully ripened Bartlett pears are thoroughly washed to remove spray residues. Small pieces not suited for packing as "halved" pears are trimmed, chopped, preheated and pressed through cloth, and the resulting juice is run into cans. The cans are sealed and heat processed.

Analysis (submitted by distributor).—Moisture 87.6%, total solids 12.4%, ash 0.3%, fat (ether extract) 0.5%, protein (N × 6.25) 0.3%, crude fiber 0.04%, carbohydrates other than crude fiber (by difference) 11.3%, invert sugar 7.85%, sucrose 1.05%.

Calories.—0.5 per gram; 14 per ounce.

THE CASE OF ASA BRUNSON VS. MORRIS FISHBEIN

(Continued from page 59)

Tuesday, May 30, 1939—Afternoon

Dr. Asa Brunson resumed the witness stand and further testified as follows:

ON CROSS EXAMINATION (RESUMED)

Questions by Mr. Brown:

Mr. Brown:—Your Honor, we have about three or four more questions of Dr. Brunson, and then will probably turn him over to counsel.

Q.—Dr. Brunson, you originally sued in this case for \$250,000, didn't you? A.—It was first brought for \$250,000.

Q.—Then you dropped to \$50,000? A.—That was on account of my attorney, he did that, and not me.

Q.—Who started at \$250,000, you or your attorney? A.—What is that?

Q.—Who started at \$250,000, you or your attorney? A.—My attorney.

Q.—And then he dropped it without talking to you about it? A.—Yes, he wrote—

Q.—Is any one financing this suit for you? A.—What?

Q.—Is any one financing this suit for you? A.—No.

Q.—None? No one? During all of these years you have claimed to have a remedy for the Great White Plague, for what you call the poor man's disease, and yet you have been unwilling during all of that time to make a disclosure of that remedy or make it known for the benefit of suffering humanity, is that correct? A.—That is correct, because I couldn't get a scientific investigation.

Q.—In other words, it had to be a conditional investigation as far as you were concerned, was it, is that true? A.—I wanted it investigated.

Q.—Investigated only on your terms? A.—What is that?

Q.—Investigated only on your terms? A.—And my terms were very fair.

Q.—What body could investigate it besides the American Medical Association? A.—Well, Rockefeller Foundation.

Q.—Did you have it examined by them, or offer it to them? A.—No. I wrote them and they told me if I would submit the formula to them in about two years they would tell me what the results would be.

Q.—You refused to submit the formula? A.—I told them I would go up and make the medicine for them, and let them try it out for ninety days, and then I would give them the formula.

Q.—What did they say to that? A.—They wouldn't do it.

Q.—It had to be a conditional examination then, or investigation? A.—I wanted a fair examination.

Q.—And you wanted to be the judge of that, didn't you? A.—No, sir, there was doctors that they had observing the patients that I would treat, they would be the ones.

Q.—You would not turn it over to them on their conditions? A.—I never would give the formula up.

Q.—Have you submitted it to any one else? A.—Do you mean the formula?

Q.—Yes? A.—No, I have not.

Q.—Did you submit a proposition to any one else? A.—I did to the Public Health Service, and I went further with them than I did with any one.

Q.—And you had your own conditions attached to that in submitting it, didn't you? A.—I first wrote to General Cummings and told him I would like to treat—

Q.—Don't tell what you told him. You did want to submit it on your own conditions? A.—Certainly.

Q.—You would not conform to the conditions of the Public Health Service? A.—I offered it.

Q.—You would not conform to the conditions of the Public Health Service? A.—I think it was very close to it, if you want me to tell you.

Q.—Did they submit a proposition to you? A.—They told me to write the American Medical Association and get an investigation by them, that they could not use an unknown formula on the patients in the hospitals of the Public Health Service.

Q.—And upshot of it is that you would not submit it to any authorized body, would you, any duly constituted body? A.—No, but I offered to give it to General Tappan if they would investigate it.

Q.—Upon your conditions? A.—(No answer).

Q.—Upon your conditions? A.—It was partly upon their conditions if I gave Dr. Tappan the formula.

Q.—You attached conditions to it yourself? A.—The condition was they would use the medicine for ninety days.

Q.—Without knowing what the formula contained? A.—The condition was they would use the medicine for ninety days and at the expiration of that time Dr. Tappan could have the Surgeon General—the formula and the results he observed from the treatment of patients.

Q.—Without knowing the formula? A.—Dr. Tappan would have known it.

Q.—You refused to submit the formula to him in the first instance? A.—At the first instance I did.

Q.—Didn't they tell you they would not try it until you submitted the formula itself? A.—No. They told me to take it up with the American Medical Association.

Q.—Which you were unwilling to do? A.—There wasn't anything said about revealing the formula in the first letter I wrote them.

Q.—Did you submit it to anybody else, any other body? A.—No, not directly, in regard to treating—yes, I did, to the state medical society when they met here a few years ago.

Q.—They didn't take it up? A.—I wrote the president, sent it to him by a messenger of the Western Union, and got a receipt for the letter; told him I would appreciate it if he would appoint a committee of three to come and ascertain my theory of treatment for tuberculosis, and if he was satisfied and would make an appointment with the state sanatorium I would treat fifty or 100 patients without charge, and at the expiration of ninety days I would give him the formula to make public to the world.

Q.—They refused to do anything unless you gave them the formula? A.—They never said anything about the formula. They didn't even have the courtesy to reply to my letter.

Q.—How long have you been living in El Paso? A.—What?

Q.—How long have you been living in El Paso? A.—I think I have answered that a dozen times. I have been here since the 15th of January, 1924.

Q.—Where have you lived in El Paso? A.—I have lived in several different places.

Q.—Where are you living now? A.—I am living at the Cortez Hotel.

Q.—How long have you been living at the Cortez Hotel? A.—About two years and seven months.

Q.—What apartment do you occupy there, what space? A.—I have got Apartment 202, one bed room, living room, kitchenette and dinette.

Q.—Where did you live prior to that? A.—I lived on Pershing Drive.

Q.—And prior to that in Kern Place? A.—And prior to that in Kern Place, lived in two places in Kern Place.

Q.—And how long have you had your present rooms in the Caples Building? A.—Well, ever since I have been here. I was in the First National Bank Building four or five months and moved to the Caples Building and have been there ever since.

Q.—How many rooms do you occupy in the Caples Building? A.—I have three rooms.

Q.—Do you own an automobile? A.—Well, I do and I don't. I owe more on it than it is worth.

Q.—That is all.

ON RE-DIRECT EXAMINATION

Questions by Judge Sweeney:

Judge Sweeney:—I would like to get Exhibit No. 6. May it please the Court, this was offered by the defendant this morning and exhibited to the jury, but not read. I want to advise the jury what it is in it.

Mr. Brown:—Judge, the back part of it, the jokes are not in evidence at course.

Judge Sweeney:—No, I am not going to read the jokes, just the front page. The Court:—Very well. Proceed.

Judge Sweeney thereupon read Exhibit D-6, as follows:

"Dr. Asa Brunson discovers Treatment for Tuberculosis Eight Years ago.

"Dr. Asa Brunson of El Paso who originated a unique and successful method for the treatment of tuberculosis, eight years

BRUNSON VS. FISHBEIN

131

ago has become internationally famous on account of the results obtained in treating thousands of cases in all stages of the disease.

"The doctor, who has been practicing medicine for thirty years, is a graduate of the Memphis Hospital Medical College class 1899. He served as captain in the Medical Corps during the World War and for eight years has limited his practice to the treatment of tuberculosis exclusively.

"Dr. Brunson attributes his success in the treatment of tuberculosis, where other doctors have failed, to the fact that they have been constantly trying to eradicate the tubercle bacilli instead of the pus germs which he believes are entirely responsible for the bad symptoms of the disease.

"His theory of tuberculosis is that the pus germ plays a much more important part in the disease than the tubercle bacilli and he has proved conclusively that when the pus can be eliminated and the pus germs rendered inactive, patients even in advanced stages of tuberculosis recover very rapidly.

"The treatment is administered by means of inhalation and causes no irritation or reaction and the patient is not confined to a sanitarium or hospital but simply visits his suite of offices twice daily for treatment, when convenient, however, Dr. Brunson's treatment may be taken by the patient at home and at the present time the doctor is mailing medicine to patients from coast to coast and from the Canadian border to the Gulf of Mexico.

"Hundreds of tubercular patients who have taken Dr. Brunson's treatment have returned home and resumed their former occupations in all walks of life. Their letters of appreciation and recommendation flow into the office daily and it is a source of great satisfaction to the doctor to know that tubercular sufferers who once had little hope now enjoy the best of health.

"Dr. Brunson is offering to disclose his formula to the world after a ninety-day, scientific investigation by the medical association or any other scientific research foundation or organization inasmuch as there are millions of cases of tuberculosis in the United States and the death rate is larger than from any other disease, it would seem vitally important that such an investigation be started immediately in order that those suffering from tuberculosis throughout the entire world might take immediate advantage of Dr. Brunson's successful method of treatment, especially since he offers to pay all expenses of such an investigation."

Judge Sweeney:—Now, on the same page:
"Out of Work Four Years, Spent Thousands of Dollars,
Cured in Three Months.

"Roswell, New Mexico,
"December 1, 1926.

"I came to El Paso two years ago with an advanced case of tuberculosis. I had been sick for thirteen years at that time. I took the sanitarium treatment for fourteen months, had a hypodermic every day and after this length of time, my doctor found a great deal of tuberculosis left in both lungs, and told me not to be out of bed more than three hours a day and not to walk out of the house.

"After being in idleness for over four years, and spending thousands of dollars for different treatments, I felt very discouraged. Then I decided to try the Brunson treatment.

"I took two treatments a day and at the end of three months I was cured. Then I made a trip back to New York and caught a bad cold and when I got back to El Paso my lungs were in bad shape again.

"I took the Brunson treatment again, and in three weeks my lungs were clear, and I am well and working every day.

"It is a great pity that the Brunson treatment and its wonderful results are not known far and wide over the world for many tubercular patients could regain their health and live useful lives after taking this treatment.

"Mr. Frank Ehret."

Q.—Now, Doctor, you were examined at some length by Mr. Brown with reference to your education. State whether or not you took the usual and ordinary course that was prescribed for young men studying medicine at the time when you took up the study of medicine? A.—I had a much higher education than the majority of men that were admitted to study medicine at that time.

Q.—You studied medicine in the Medical Hospital College? A.—Memphis Hospital Medical College. It is now the University of Tennessee. They recognize that school as a first class medical college.

Q.—Did you get a diploma from that college, and that college was afterwards merged into the University of Tennessee, was it? A.—Yes, sir.

Q.—State whether or not you are now recognized as a graduate of that institution? A.—I am recognized as a graduate of the University of Tennessee.

Q.—Doctor, some questions were asked here with reference to a man by the name of O'Hara, whether or not you had treated him during May and June for approximately forty-five days during the year 1938, is that a fact? A.—Yes, I treated him from the 9th of May until the 24th of June.

Q.—State what his condition was when he came to you? A.—He had a moderately advanced tuberculosis, and on account of his habits he was getting worse, as he told me, all of the time. He could not digest his food, he had difficulty in sleeping. Q.—Did he have hemorrhages or temperature? A.—He had temperature the first day that he came to me. As for hemorrhages, I don't know whether he ever had a hemorrhage or not.

Q.—Did he state to you that he had? A.—He didn't tell me that he had when I was taking his personal history.

Q.—Had he been in any institution in El Paso? A.—He was in the Hendricks-Laws Sanitarium a year before.

Q.—Did he state how long he was in there? A.—I don't remember just exactly; four or five months though.

Q.—Did he state why he returned to you from Chicago for you to treat him? A.—He stated to me the reason he came, he heard me—

Mr. Brown:—If the Court please, we think that is purely hearsay. We did not go into those details ourselves, and we think it is objectionable, and therefore we object to it.

The Court:—What are the grounds of your objection, hearsay?

Mr. Brown:—We object to it. Yes, sir.

The Court:—The Court sustains the exception.

Q.—Dr. Brunson, how long did you treat him? A.—Forty-five days.

Q.—What was his weight when he first came to you? A.—His weight was 150 pounds.

Q.—What was his weight when he left? A.—The evening of the 24th of June he weighed 158 pounds.

Q.—What was his condition, physical condition? A.—Well, he looked a great deal better, but he lacked a great deal of being well.

Q.—Had he or not improved? A.—He had improved or else he would not have gained weight.

Q.—How was he with reference to eating and sleeping and resting? A.—What?

Q.—How was he with reference to eating and sleeping and resting? A.—Oh, after I gave him a prescription his stomach got all right, and he was sleeping as well as any one.

Q.—Dr. Brunson, the formula that you used on Mr. O'Hara, state whether or not it was the same formula that was used both prior and subsequent to the statements of the telegram from Dr. Fishbein to DeWitt Wallace? A.—It was the same formula.

Q.—You have treated many patients during the last twelve months or two years for tuberculosis, have you not? A.—I have not treated so many.

Q.—Do you know Odell Massey? A.—I do.

Q.—Was he a patient of yours? A.—He was.

Q.—When did you commence the treatment of Mr. Massey, and tell what his condition was when he first came to you?

Mr. Brown:—Your Honor please, now these specific instances there are a lot of collateral matters of inquiry, and we are going to object to testimony with reference to specific instances; it does not tend to throw any light upon the issues in this case, and will involve trying out of some particular cases and the facts upon which he predicates his answers.

Judge Sweeney:—Now, may it please the Court, I would like to respond to that.

The Court:—Very well, the Court will hear from you.

Judge Sweeney:—The basis of the suit is the therapeutic value of his formula, and all of the testimony before us now is—

The Court:—We haven't got the formula yet.

Judge Sweeney:—No. The therapeutic value—I am speaking of the therapeutic value of any formula or any medicine, irrespective of whether or not you know what it is, can only be ascertained by trying that medicine out. Now, that is the testimony that is before us. I seek to ascertain from him that he has treated, the condition of those patients prior to the time that he commenced treatment, the condition of those patients when he charged them. That is for the purpose of showing the therapeutic value of the medicine that he administered, and that it is not a dangerous fake.

Mr. Brown:—Just one moment, your Honor. It appears to me this is argument based on the facts, and so forth, and is improper at this time in this court room right in the presence of the jury.

The Court:—Gentlemen of the jury, you may retire from the court room and remain outside in the hall a few moments, subject to call.

The jury thereupon retired at 2:25 p. m., whereupon the following proceedings were had out of the hearing and presence of the jury:

The Court:—Now, gentlemen, in anticipation of not only the question here raised but as to the question of offering of any testimony by lay individuals, we will consider them both at this time and I will hear from you and then will hear from counsel for defendant.

Mr. Quaid:—Your Honor, we believe that the condition of the record at this time is that the best evidence is the use of his treatment. Now, we propose to show by these witnesses, by him, who is an expert, that is from the legal standpoint, being a physician and surgeon, that he can testify as to these patients that came to him, how sick they were, and what their condition was, and what he did for them, and then what the result was; and the best evidence under the testimony so far is the use of the medicine, and I think that is at this time very relevant to the issues in this case; the question being whether it is a dangerous fake or not. If we can show we used this on patients, human beings, and show that it was helpful, and in some cases curative, then it should be admissible on the main issue in the case, and relevant to that issue. We recognize a patient can't come in and give a conclusion of it, that he did this or he did that, but we do believe that a doctor, who is an expert witness, can testify that a patient came in to him and tell what that patient's condition was, as an expert, and then show what he did for that patient, and how that patient improved or did not improve, or what the condition was after a certain amount of treatment. Of course, we think that the patient, or any intelligent observer, could testify as to the taking of the treatment, and what the condition, what physical symptoms were, whether he had fever or not, whether he had a cough, and when the treatment ended whether they still had that cough, whether they still had that fever, or what the physical symptoms were. Of course, we recognize the ordinary observer cannot testify as a medical or legal conclusion, but we do believe that a physician and surgeon can testify to those matters, that that is the best evidence.

Mr. Reynolds:—Your Honor please, this is not the first time this very situation has arisen in connection with libel suits.

The Court:—The Court could anticipate that.

Mr. Reynolds:—It does happen to be a case, however, on which there isn't much in the books. We are citing for the Court's consideration the statement contained in *Jones on Evidence*, section 49, I believe it is wherein the conclusion is that, for instance in a malpractice suit—no, this was in a libel suit—the defendant was not allowed to put on evidence of this nature and allow lay witnesses to testify. Now, if a defendant cannot do it the plaintiff should not be permitted to do it.

The Court:—Just a moment. We are discussing here, and the Court wants to hear from you, with reference to two phases. The Court merely suggested that a distinction might be raised between a layman testifying, being permitted to testify, and a doctor who has treated that man. . . . The question we are first confronted with here is the doctor testifying as to his treatment of a patient. The question here suggested by counsel for defendant is that Dr. Brunson should not be permitted to testify with respect to specific cases.

Mr. Reynolds:—That is correct.

The Court:—The Court thinks possibly latitude of testifying generally is broader perhaps than undertaking to testify with reference to particular individuals.

Mr. Reynolds:—I merely undertook to discuss the wrong phase first.

The Court:—All right.

Mr. Reynolds:—With respect to specific instances, the greatest objection to such testimony in a suit of this nature is the fact that it forces the Court to try some fifteen different law suits if there are fifteen different patients involved, under circumstances wherein the defendant has had absolutely no opportunity to examine the patients before the treatment, to examine the remedy or method of treatment, or to have an examination of the patient subsequent to the treatment. There is no sort of guaranty of trustworthiness other than the fact that the plaintiff himself said the man was sick, I diagnosed it as such, I treated it as such, and now he is well. We have no way under the sun of going into that without all of these collateral possibilities. It amounts to trying a different law suit in each case. The Courts have been very, very definite in condemning an issue of that type. Had the defendant here ever had opportunity to present evidence to the contrary under all rules of evidence of course this might be an admissible line of testimony, but when we have none and we have no way in which to get it, it has the same purpose as allowing self-serving documents to go into evidence.

In *Jones's Hand Book on Evidence*—the section to which we refer is 149, on page 761—the statement is "Thus where slanderous words charged a physician with a want of skill, it was held inadmissible to show by way of mitigation specific instances of malpractice." That is where the defendant himself on the other side of the case attempted to introduce the same type of evidence. Then this further statement, from the previous page, 760: "But in such cases the evidence must be confined to the general reputation of the plaintiff, before the publication of the slander or libel, and such reputation cannot be shown by specific instances of his misconduct." We all know on the question of reputation specific instances are not admissible.

The Court:—The Court does not quite see that any of the authorities cited apply very closely to the question that is before the Court. The Court will eliminate right now, as far as that is concerned, lay testimony; the testimony of lay witnesses will not be admitted. They are individuals

who might have received this treatment, there are so many things that might have entered into their condition, and so forth, that they are not qualified. The question is, you have a qualified witness on the stand here, for the purpose of admissibility of the testimony you have a qualified witness, qualified in a manner to permit him to testify as an expert. Now, he is testifying, he has testified already in this case that he has treated thousands of individuals and benefited them; that testimony was admitted without objection by counsel. The Court is not going to worry about trying several thousand cases at this time. The question before the Court, and which this Court is going to rule on, is whether he should be permitted to testify to a few specific cases. The Court may possibly permit that; if he does it will be limited to that.

Mr. Reynolds:—Now, your Honor, may I ask one thing there before we go any further, if that is to be done and specific instances are to be cited—

The Court:—You may make your argument. You may not question the Court.

Mr. Reynolds:—Well, if that is to be done, and specific instances are to be cited, the defendant wishes the Court to exercise his discretion under the new rules and allow opportunity for examination of those very patients, so that we may have some means of cross examining or rebutting the testimony; otherwise there is no way that we can reach it at all.

The Court:—The Court will perhaps undertake to protect that in a way. The Court will exercise the powers of discretion to a certain extent in certain matters with reference to evidence. As illustrating what the Court has in mind, if the defense, for instance, had an individual who had been under observation of several physicians who are qualified as physicians, who might testify with reference to their observations and examinations of the parties made at the same time perhaps, the Court thinks there is testimony already in here, without exception by counsel for defendant, much broader than any in some specific cases in which the individuals are here. This Court will say that the Court will limit the testimony here by this witness to some few individuals, specific individuals, who are within this community and who will be named by him, and limit that to a very few as far as that is concerned.

Judge Sweeney:—I didn't hear the last.

The Court:—The Court will limit it to a few, some six, seven or eight, right here in this community, that will be examined by defendant if they wish, although the Court does not see that meets the situation now, at this time. I believe it is stated in many War-Risk cases that the Court may take judicial knowledge of certain tubercular or consumptive conditions and these different stages, incipient stage, different stages and advanced stage. There are conditions under which they are treated and many things that enter into it. All right, gentlemen, the Court will limit you to about six—start with five, will limit you to five.

Judge Sweeney:—Five, all right, sir.

The Court:—And that shall be testified with reference to by this doctor.

Judge Sweeney:—May I consult the witness?

[Judge Sweeney consulted the witness in regard to testimony to be introduced.]

Q.—Doctor, do you know O'Dell Massey? *A.*—I do.

Q.—You treated O'Dell Massey for tuberculosis? *A.*—I did.

Q.—State the facts with reference to his treatment, his calling on you, his condition and what his symptoms were, and how long he was under your treatment and what the result was.

Mr. Reynolds:—May we ask counsel to confine his questions to one single interrogatory in this examination.

The Court:—Yes.

Q.—Where did you make the first diagnosis of Mr. Massey? *A.*—About 17½ miles below here on what we call the North Loop Road.

Q.—What were the circumstances under which you made it? *A.*—I was called by a friend of theirs that told the father-in-law of Mr. Massey—

The Court:—No hearsay, a direct response.

Q.—You went to his house? *A.*—I went down to his home where he was living.

Q.—Did you diagnose his case there? *A.*—I made a diagnosis of pulmonary tuberculosis far advanced.

Q.—What were his symptoms at that time? *A.*—He was delirious at that time. I couldn't talk to him at all; I had to get the history from his wife.

Q.—Did you commence the treatment? *A.*—I commenced the treatment right away.

Q.—Did he respond to it or not? *A.*—He responded very rapidly.

Q.—Within how long? *A.*—In about six weeks he was able to come to the office, 17½ miles.

Q.—How long did you continue to treat him? *A.*—About five months.

Q.—Did you finally pronounce him cured or not? *A.*—I did.

Q.—What was his condition when you pronounced him cured? *A.*—Well, he looked about as well as any one; from all examinations I could make, I couldn't find anything wrong with him.

Q.—What did he do after you had pronounced him cured?
A.—After I dismissed him?

Q.—Yes. A.—He continued to work, I think made the crop he was going to make that year.

Q.—Has he taken out life insurance since that time?

The Court:—You can't drift off into that; the Court will interpose an objection on the Court's own account, in the interest of time.

Judge Sweeney:—That was for the purpose of showing he was examined by other physicians and pronounced cured.

The Court:—That is hearsay.

Q.—Do you know Mrs. Dora Rachels? A.—I do.

Q.—Where does Mrs. Rachels live? A.—At this time she is living down the valley about 5 or 6 miles.

Q.—When did you first treat her? A.—I first treated her with the Holderness treatment in the summer of '21 or '22, I have forgotten whether the spring of '22.

Q.—How long did you treat her? A.—I think for several months.

Q.—What were her symptoms? A.—Well, she had every symptom of advanced tuberculosis, hemorrhages and temperature and night sweats.

Q.—What was her weight? A.—I don't suppose she weighed over 80 pounds.

Q.—You treated her how long? A.—I treated her with the Holderness treatment about three months, the best I can remember.

Q.—Then what? A.—She returned to me the latter part of January '24, and she was able to come to the office, but she was not well, and I treated her for several months and then dismissed her as cured.

Q.—What treatment did you finally treat her with? A.—I used the treatment I am using every day for tuberculosis.

Q.—Is it the Holderness treatment? A.—No, it is my treatment.

Q.—Was Massey's treatment your treatment or Holderness's? A.—My treatment.

Q.—Does Mrs. Rachels live here in El Paso? A.—She lives about 5 miles below town at Ascarate.

Q.—How long is it since you dismissed her as cured? A.—Oh, I dismissed her some time in the summer of '24.

Q.—Have you contacted her recently? A.—Yes, I have.

Q.—What is her condition now? A.—She looks as well as any one does for her age and the amount of work she has to do.

Q.—Do you know Mrs. C. H. Boyce? A.—I do.

Q.—Where does she live? A.—She lives in El Paso.

Q.—What is her occupation? A.—I think she is a bookkeeper.

Q.—For what, for whom? A.—The Popular Dry Goods Company.

Q.—Did you diagnose her case when she first came to you? A.—I did.

Q.—When was that? A.—That was early in '25 or '24, a short time after I came back.

Q.—Had she been treated for anything, for tuberculosis, prior to your treatment? A.—She was treated by Dr. R. B. Homan—

Mr. Reynolds:—We object to that question and answer; there is no relevancy in this case and incompetent.

The Court:—Please state your grounds.

Mr. Reynolds:—The grounds are it is purely hearsay, this witness is not competent to testify to.

The Court:—The Court sustains the objection on the ground of hearsay.

Q.—How long did you treat her? A.—I didn't treat her but a very short time, two or three months.

Q.—Did you finally dismiss her? A.—What?

Q.—Did you finally dismiss her? A.—I did.

Q.—How long ago was that? A.—That was in—let's see, April or May 1924.

Q.—She is living here now? A.—Yes.

Q.—What is her condition, physical condition? A.—Perfectly well.

Q.—Do you know Mrs. J. E. Crow? A.—I do.

Q.—Where does she live? A.—She lives in El Paso.

Q.—Did you ever treat her for tuberculosis? A.—I did.

Q.—When did you make your diagnosis? A.—You say where?

Q.—When? A.—I have forgotten now whether in '27 or '28.

Q.—How long was she under your treatment? A.—She wasn't under my treatment but a very short time; I think two months or possibly a little longer.

Q.—What was her condition when you started treatment? A.—Well, she had moderately advanced tuberculosis.

Q.—You dismissed her in two or three months, you say? A.—I think less than three months I dismissed her as cured.

Q.—She resides here? A.—Yes.

Q.—What is her physical condition now? A.—Well, she is about as well as any one I know.

Q.—Ever have a recurrence of tuberculosis? A.—No.

Q.—Do you know John A. Lozier? A.—I do.

Q.—Where does he live? A.—He lives in El Paso.

Q.—Did you ever treat him for tuberculosis? A.—I did.

Q.—What were the symptoms? A.—What is that?

Q.—What were his symptoms? A.—He had tuberculosis of the throat and tuberculosis of both lungs.

Q.—How long previously had he had it, previous to your treatment? A.—Two or three years.

Q.—You treated him how long, Doctor? A.—I treated him for about two years.

Q.—What was the final result of your treatment? A.—His throat was cured, his lungs cleared up.

Q.—How about his lungs? A.—His lungs cleared up, he has been driving a taxi four or five years.

Q.—Now, these individuals that I have asked you about, Doctor, they were all treated by you under your system? A.—They were all treated with my treatment.

Q.—And it has been quite a number of years since you treated them? A.—Yes, it has been a long time.

Q.—And their physical condition is good? A.—They are still well.

Q.—They have not had a recurrence of their former difficulty? A.—They have not.

Q.—Is that the same formula you were using in May 1938? A.—Same formula, yes.

Judge Sweeney:—I would like to put in the date of the telegram, January 1938.

The Court:—It is already in evidence.

Judge Sweeney:—Yes, but I just wanted to connect that up.

ON RE-CROSS EXAMINATION:

Mr. Brown:—I would like to ask that Mr. Reynolds be permitted to examine the witness about the specific instances and I be relieved at the present time.

The Court:—All right, go ahead and examine the witness.

Questions by Mr. Reynolds:

Q.—Dr. Brunson, how old was this patient O'Dell Massey when she first came to you—when he first came to you? A.—You are trying to tax my memory, I don't remember.

Q.—The approximate age? A.—About 30 years old.

Q.—And what diagnosis did you make at that time? A.—Active pulmonary tuberculosis.

Q.—How did you determine that? A.—I determined that by the history that his wife gave me, by stethoscope examination, and taking his temperature and pulse.

Q.—Did you take any x-rays? A.—No, he was too far down in the country and too poor to take them.

Q.—What type of rales did you hear in examining his chest? A.—I heard all kinds.

Q.—That means all kinds there are? A.—Yes, he had every kind you could think of.

Q.—Every type of tuberculosis you can think of? A.—What?

Q.—Every type of tuberculosis you can think of in the lungs? A.—No, I didn't say that, I said he had all different kinds of rales, there isn't but one type of tuberculosis.

Q.—Doctor, did you have a sputum examination of him made? A.—I didn't, it wasn't necessary.

Q.—Why wasn't it necessary? A.—Because any one, a newsboy, could tell he was in the last stages of tuberculosis.

Q.—From the temperature and from listening to his lungs and from his pulse? A.—An objective symptom.

Q.—Those are all objective symptoms, are they? A.—Those are objective symptoms.

Q.—You made no further examination? A.—It wasn't necessary.

Q.—Do you have his history in your possession? A.—I don't know that I have, but he had pneumonia in Houston, Texas, went to a hospital, and after he recovered from the pneumonia he had tuberculosis.

Q.—Just a minute, answer the question.

The Court:—Read the question. (Question read.) What is your answer to that question?

A.—I think I have, but I haven't it here in my pocket.

Q.—Are you willing to produce it for counsel for the defendant to inspect, Doctor, in connection with this case? A.—Yes, I am.

Q.—And is the same true of the history of Mrs. Rachels? A.—Yes.

Q.—And the history of Mrs. Boyce? A.—Yes.

Q.—And the history of Mrs. Crow? A.—Yes.

Q.—And the history of Mr. Lozier? A.—Yes.

Q.—Now, Doctor, all of these cases you definitely diagnosed as pulmonary tuberculosis? A.—Absolutely.

Q.—All of them, after your treatment, you discharged as absolutely cured? A.—I did, as far as I could tell.

Q.—Aren't you saying today that they are cured, then? A.—Yes, they are cured.

Q.—When you discharged Mr. Massey as cured, did you have any sputum test made? A.—No, I did not.

Q.—Did you have an x-ray made? A.—It wasn't necessary, he was taking out old line life insurance.

Q.—Just a minute. We move to strike the answer.

The Court:—Counsel will please address the Court, and not address an objection simply to the witness or to the answer of the witness. The Court will say to this witness, when counsel asks a question, the witness will answer the question in as direct form as you can, you will not volunteer testimony along some line counsel hasn't asked.

Q.—Doctor, your answer to whether or not you had x-rays made was no, is that right? A.—For who?

Q.—For O'Dell Massey. A.—I didn't have an x-ray made, but he had them made.

Q.—Did you see them? A.—I did.

Q.—Who made them, if you know? A.—I think Dr. George Turner made the pictures.

Q.—What examination did you give Mr. Massey at the time, just before you discharged him as cured? A.—I went over him with a stethoscope.

Q.—Is that all? A.—That was all that was necessary.

Mr. Reynolds:—I am sorry, Your Honor, I must object to this statement that is all that is necessary, because it is purely a conclusion.

The Court:—The Court will say to the witness, when you answer a question, stop with that answer. Don't say it is not necessary. You may think in your own mind it is not. That is not part of the question propounded to you.

Witness:—All right, I will not.

Q.—Regarding the case of Mrs. Rachels, how old was she, as near as you can tell, when she first came to you for treatment? A.—I suppose she was about 40 years old in '21.

Q.—And did you make any examination of her at that time in diagnosing her condition? A.—No, I wasn't practicing medicine then; the doctor working for Holderness and myself made the examination.

Q.—Did you see him? A.—I didn't see him when he made the first examination.

Q.—Did you ever examine that woman during the course of your treatment? A.—I did.

Q.—After you had your own license, I suppose, is that it? A.—After I received a license.

Q.—And what kind of examination did you give her? A.—I examined her with a stethoscope, took her pulse, temperature and quizzed her about her condition.

Q.—Maybe we can shorten this up. On all of these patients, was your examination before your treatment practically the same, that is, pulse, temperature and listening to the chest? A.—Yes.

Q.—None of them were cases in which you had a sputum analysis or an x-ray before the treatment? A.—No, I didn't.

Q.—And none of them were cases in which you had an x-ray or sputum analysis at the time you discharged them, is that correct? A.—Well, now, I don't remember out of the five, I may have, I don't remember whether I did or not.

Q.—Who would have made them? A.—Well, they would have been made by the ones I sent them to, either Cathcart and Mason or Waite or Dr. Turner, but I don't think at that time that Dr. Turner was making x-ray pictures.

Q.—Well, now, do you recall whether or not you had any x-rays or sputum examinations made of Mrs. Boyce, Mrs. Crow or Mr. Lesser—Lozier, any of those three, do you recall? A.—No, I don't remember having them made.

Q.—Now, Doctor, have you ever performed an autopsy on a person who died with tuberculosis? A.—I haven't personally, but I have seen several.

Q.—Have you ever seen autopsies performed on any of your patients who died from tuberculosis? A.—I saw two.

Q.—Will you tell us what it is that you see in the lung in an autopsy of a person who has tuberculosis, an active tuberculosis? A.—You mean in the autopsy after they are dead?

Q.—Yes. A.—Well, in some cases you find cavitation, others you find pus in the bronchial tubes and bronchi, you can't see microscopically, you can't tell whether there are pus germs in the secretion or whether the tubercle bacilli are there.

Q.—Can you see the tubercles? A.—Well, if you look for them right hard, you might see them, but the two I had—can I answer this question?

Q.—Yes. A.—One was collapsed lungs, spontaneous collapse of both lungs, the patient died very suddenly. The other I saw was a patient I had treated and was apparently well, and died from acute pyelitis.

Q.—Could you see any evidence of tuberculosis in that last patient? A.—We saw pus, but I had had a sputum test made just a few days before her death, and I didn't find any tubercle bacilli at all.

Q.—Can you see tubercle bacilli on an autopsy through a microscope? A.—If you get some of the pus before they have been embalmed, you can find them, but after they are embalmed, you couldn't.

Q.—You spoke about this one person having collapse of both lungs. Do you know what caused that? A.—What caused the sudden collapse?

Q.—Yes. A.—It was this tubercular condition. I don't think any one has ever determined yet just what causes a sudden collapse; it is very rare.

Q.—Now, Doctor, will you explain to the jury, I don't think we have gotten this clear yet, will you explain to the jury just what a tubercle looks like? A.—What a tubercle looks like?

Q.—Yes. A.—It is round, looks like a little hickey on your face; it is round, you may see a number and may see some so small you can hardly detect them, and some so large you can see them very plainly with your eye. That is the house that the tubercle bacilli build.

Q.—Are any of those open, running? A.—I have never seen one, I have never seen a tubercle inflamed.

Q.—Where does pus come in connection with that? A.—It doesn't come in connection with that. Without the tubercle bacilli you wouldn't have tuberculosis.

Q.—Say you have a tubercle, it is a little lump, where is the pus, inside of the lump? A.—No, there is no pus inside.

Q.—Where is this pus you have been talking about? A.—The pus germs are buried down into the lung, in the lung tissue, and there is destruction of tissue, that mucus is what we usually call pus, that gets into the smaller bronchi and larger bronchial tubes, into the bronchus, and is thrown off or expelled by coughing.

Q.—If you have never seen a tubercle inflamed, and the pus germs aren't in or near that tubercle, what relation have the two? A.—What relation do the two have?

Q.—Yes. A.—They haven't any relation with the exception—can I explain this?

Q.—Certainly. A.—When you have irritation of the lung, caused from tubercle bacilli, it makes a good field for pus germs, and every breath we breathe we are breathing from 500 to 3,000 pus germs, a patient's resistance is lowered, they get in the fertile field from irritation of the tubercle bacilli and become active.

Q.—What does? A.—The pus germs become active. A pus germ has caused every symptom that is manifested in the disease and the cause of every death, where they die from tuberculosis.

Q.—Now, Doctor, what is it that causes the fertile area where the pus germs become active, is that connected with the tubercle? A.—No, but the irritation that is caused from the tubercle bacilli. That isn't thoroughly understood, just what damage the tubercle bacilli does; we do know that pus infection causes every symptom, decaying of the lung, destruction of the tissue, cavitation, and when you get cavitation and it opens a blood vessel, if a small one, you have a small hemorrhage, if a large one, you have a large hemorrhage.

Q.—Doctor, is the tubercle bacilli the only thing that causes these fertile fields and allows pus germs to become active in the human body? A.—No.

Q.—There are many such things? A.—You can have that from lung abscess following pneumonia or following flu pneumonia, which is not really true pneumonia.

Q.—As far as your treatment is concerned, what you are controlling is the pus germ condition itself? A.—The pus germ is the germ I am fighting, and I never saw under a microscope a specimen of sputum of a tubercular that the pus germs didn't

predominate, and, inasmuch as the doctors had tried everything known to medical science to cure tuberculosis, I came to the conclusion that they never had tried to eliminate the mixed infection, and that was the cause of my working and trying to find a cure for the disease.

Q.—Now, your theory of eliminating the mixed infection, by which I assume you mean pus germ infection, is through an expectoration? A.—Absolutely, that is my theory and I have proved that theory, because when we stop the activity of the pus germs, patients invariably get well.

Q.—That would apply, as far as your remedy is concerned, to lung abscess and conditions following pneumonia? A.—Bronchitis.

Q.—Asthma? A.—It depends on what kind of asthma.

Q.—What kind of asthma? A.—Bronchial asthma.

Q.—Doctor, on these two autopsies of your patients that you saw, did you see any cavities in either one of them? A.—No, I did not.

Q.—Did you see any fibrous tissue? A.—I did not.

Q.—Did you find any calcified nodules? A.—We weren't looking for that.

Q.—Did you see any? A.—I wanted to see what the cause of sudden death was with the one that had both lungs collapsed; that is all we were looking for. When we found that, we closed the patient up. The other patient—do you want me to answer?

Q.—Yes. A.—The other was pyelitis, that is, inflammation of the kidney. The young lady died so quickly and ran such an excessive temperature for six or seven days that I wanted to know just what the immediate cause of her death was. We found one kidney was entirely destroyed, just a shell, and was full of pus. The other kidney was very much inflamed, that caused suppression of the urine, and the highest temperatures nearly that we have are caused from that infection of the kidney.

Q.—Doctor, then you did not see any pathological study made or make any yourself of either of these patients in regard to tuberculosis? A.—Well, with the one I told you we held an autopsy to find out about the kidney, I had a blood culture made by Dr. George Turner, I had a sputum examination by Dr. Turner, Dr. E. J. Cummins was in consultation with me, he examined the young lady and he was just as far lost as I was. It was very hard to make a diagnosis. We got a specimen of the urine and didn't find albumin, sugar or casts; consequently we didn't know whether it was a case of pyelitis or not. With pyelitis you usually find pus in the urine.

Q.—Doctor, in that case did you find any fibrous tissue in the lungs? A.—Didn't look.

Q.—Did you find any calcified nodules—you didn't look for calcified nodules or cavities? A.—No, what we wanted to know was whether or not the kidneys were affected, and I believe Dr. Waite—

Q.—Doctor, we are getting afield, I want to bring it back to a question of tuberculosis, if you don't mind. My question is, in that particular case, you didn't make a pathological examination of the person's lungs? A.—After death?

Q.—Yes, of the lung? A.—Yes. Do you want me to tell how that was done?

Q.—I want to know what you found, if you found fibrous tissue or calcified nodules? A.—No, the only thing we found, she had been embalmed, Peak-Hagedorn didn't know we were going to hold an autopsy and had her embalmed. We found pus when we cut in the left lung. We saw pus; that is as far as we went.

Q.—Is that a person you had discharged as cured of tuberculosis? A.—I did.

Q.—In that respect, you found, after death, there was still some evidence of tuberculosis? A.—We couldn't prove that, because we couldn't examine the secretion then in the lung. We couldn't say whether it was tuberculosis or not; tuberculosis did not kill her.

Q.—Dr. Brunson, I forgot to ask you how old was Mrs. Boyce when you first diagnosed her case? A.—I would have to make a guess on that.

Q.—Approximately? A.—Twenty-two or twenty-three.

Q.—How old was Mrs. Crow? A.—Mrs. Crow was about 25 or 26 years old.

Q.—And John Lozier? A.—I suppose that he was about 33 or 34 years old. Now, this is just from memory and I can't say that it is positive.

Q.—Doctor, will you explain to the jury the meaning of chronic fibroid pulmonary tuberculosis. A.—Do you want me to tell the jury?

Q.—Tell the jury what it is. A.—Well, it is a tuberculosis that people usually live a long time. When it becomes fibroid, that is fibrous tissue that is forming in the lung, where it has been irritated by pus germ, as much so as with the tubercle bacilli, and they will live much longer than active cases of pulmonary tuberculosis where you do not find the fibroid condition.

Q.—Then the usual case of fibroid tuberculosis, what is the age group that it covers? A.—I didn't understand.

Q.—What is the usual age group of cases of chronic fibroid? A.—You mean the age of the patients?

Q.—Yes. A.—You find more people past the middle span of life, say from 40 years up, but you find a fibroid condition in younger people, but not as often.

Q.—Now, the history of that kind of patient is that the person runs a temperature, has other symptoms, which you say are those of tuberculosis, for a while, then they may cease to have those symptoms entirely for a period of time after that? A.—I have known many people that gave a history of never running a temperature and had an advanced case of fibroid tuberculosis.

Q.—And there are cases of fibroid, chronic fibroid tuberculosis, where there are no rales you could hear with the stethoscope, aren't there, Doctor? A.—You can always get some inadvertent sounds in the lung, even if it is a fibroid; you can hear sounds you wouldn't hear in hell.

Q.—And it is true in those cases of chronic fibroid tuberculosis a person may, after having had a pulse that was not normal for sometime, may then again regain a normal pulse, is not that true, Doctor? A.—In some cases it is true. Tuberculosis is a very peculiar disease; very seldom do you find two people that manifest identically the same symptoms. It is just a disease that we, as physicians, do not understand as much about as we would like to know.

Q.—Now, Doctor, as a result of our discussion about this chronic fibroid pulmonary tuberculosis, some kind of peculiar sound in the chest that might be distinguished is the only symptom that a person might have that tuberculosis even though they had many symptoms previously. Is that right? A.—In many cases it is correct.

Q.—In many cases you do not hear the noise in the chest? A.—I never found one, a chronic case of tuberculosis that you did not find abnormal sound, regardless of how long they had it.

Q.—If you found no temperature and a normal pulse, no noise in the chest, merely by using a stethoscope you are satisfied to discharge that person as cured of tuberculosis. Is that right, Doctor? A.—If I have observed a patient during the time he came to me and I made my own physical examination and pronounced him to have tuberculosis and they ceased to cough, they were not running a temperature, their pulse normal, they were gaining in weight, they were eating well, sleeping well, I would dismiss them; but where persons could stay here any length of time I would ask them to come back and see me every fifteen or thirty days for re-examination to assure myself I had not done them an injustice.

Q.—Does that assure you that you had not done them an injustice when they come to your office and you examine them by use of the stethoscope, taking temperature and pulse and diagnose from those three things it is tuberculosis and then treat them and then at the end of the time their cough has apparently gone, appetite is better, gained weight here in Texas, and you take pulse and temperature and take the stethoscope and find them normal and hear no noise in the lung you discharge them, and if a person comes back a year later if he is not cured will he show symptoms that he is not cured of tuberculosis? A.—May I ask this? You stated people who came down here in Texas.

Q.—I do not care whether they are from here. A.—I want to get that straight the climate proposition.

Q.—No, whether they come here or not. I mean a patient you discharge as cured and a year later you see them again and they have normal pulse or approximately normal, no temperature and no sound in the lung, are you satisfied they are cured of tuberculosis? A.—Yes, that is pathognomonic. They are cured.

Q.—Doctor, I would like to ask one question. What was the name of the patient on whom you saw the autopsy who died of acute pyelitis? A.—Miss Ana Marie Hall.

RE-DIRECT EXAMINATION

By Mr. Sweeney:

Q.—What is the period of incubation in tuberculosis? A.—The period of incubation—there is not a doctor in the world can tell you. We don't know.

Q.—Is it your theory that tuberculosis is contagious? A.—Or infectious?

Q.—Or infectious. A.—I contend it is not an infectious disease because it is my belief every one has the tubercular bacilli in the system, and it is a fact you cannot contract something you already have. That is the reason we cannot determine what the time of incubation is. Now, how do you get tuberculosis? Can I answer that?

Q.—Go ahead. A.—I didn't want to get called down again.

The Court:—In view of the last statement you made so that you may understand the situation, you are now being interrogated by your counsel and the question or answer has not been objected to and you may proceed to answer.

A.—The way people contract tuberculosis, they get their resistance lowered from one of four causes, from dissipation, overwork, worry or sickness, and sickness is about 85 per cent of the cause, and when your resistance is lowered you have got the tubercular bacilli already and your resistance is lowered and it becomes active and when it becomes active and causes an irritation, breathing the number of pus germs with every breath we breathe some become active. When they do become active you have a slight consolidation in the area where the tubercular bacilli started irritation, then you have the pus infection and it is the absorption of pus that causes every symptom that is manifested in the disease, and there is no question in my mind that it has been the cause of the death of every one who died. Whenever we have pus infection any where in the body any physician will tell you it has to be eliminated before you can get well. If you have pus in your lungs you have to have that pus coming out in order to give nature opportunity to build up. If you keep it coming out as fast as it forms, your patient gets much less poison, they begin to recuperate and the scavengers of the blood, the white blood cells, destroy the poisonous germs as far as they can and that is nature trying to cure the disease. That is the cause of adhesions. You have an infection in your lung. Nature is the best doctor in the world. They form adhesions around there to prevent that poison from getting out into circulation.

RE-CROSS EXAMINATION

By Mr. Reynolds:

Q.—Dr. Brunson, from what you said, is it your theory every newborn baby contains tubercular bacilli? A.—If they haven't when they are newly born they soon have it. That can be proven by the tuberculin tests made at school.

Witness excused.

Mr. Quaid:—May it please the Court, I do not believe I am as familiar with the new rules as I ought to be. There is one matter I do not know just how it should be gotten in the record, or whether it is considered in the record. There is an admission in Defendant's Second Amended Answer in paragraph 4, that we want in the record. I would like to offer it at this time.

The Court:—You may proceed.

Mr. Quaid:—Paragraph 4, of Defendant's Second Amended Answer, plaintiff offers the following language about the middle of the paragraph: "However, defendant admits the averment that a communication was addressed to him and to the American Medical Association of Chicago, Illinois, in writing advising this defendant that the plaintiff was not using the Holderness treatment but was using a medicinal formula and system of his own and that he requested an investigation with reference thereto".

The plaintiff rests.

The jury then retired and the following proceedings were had during their absence out of their presence and hearing.

Mr. Brown:—Your Honor, at the present time we state orally the grounds for motion, which we will reduce to writing and present to the Court. We move the Court to instruct the jury to return a verdict for the defendant for the reason, among others, first, that the plaintiff has failed to meet the burden cast upon him by the law. His evidence discloses that the communication from Dr. Fishbein to DeWitt Wallace was in response to a request for information or advice, and that it was qualifiedly privileged. Being qualifiedly privileged, no cause of action can be predicated in the sending of the telegram in the absence of proof of express malice. This record is entirely wanting in any evidence whatsoever of any malice on the part of the defendant, Dr. Fishbein, toward the plaintiff. They were not even acquainted with each other, never had met and there is no showing of any reason why Dr. Fishbein should have or did have any ill will toward the plaintiff. In the case of a privileged communication the Court cannot infer

nor can the jury infer malice from the wording of the publication itself. No inference is to be drawn from the words even though they not be true, and, under the circumstances, we think that the defendant in this case is entitled to an instructed verdict and we so request at this time. Now, there are a good many authorities which deal with this question, which we think are directly in point and which we can present to the Court, if the Court so desires. At this time I will say briefly there are two authorities, one in 55 Federal (2d), and the other in 66 Federal (2d), that cover some of these issues. One of the leading cases in this case is the *Missouri Pacific v. Richmond*, found in the 73 Texas, opinion by Chief Justice Staton, who was a great justice in this state, also reported in the 11 S. W. Reporter. That case the Court lays down the rule based on an early English decision, which, we think, has been followed in practically every state in this Union. The wording of the opinion of Justice Staton in *Missouri Pacific Against Richmond* is followed identical in ruling case law and the Court states in that case—I can't quote the exact verbiage—but where there is a communication from one person to another where the persons are interested in the matters of the communication or where one has a duty to perform toward the other, either public or private, that duty being either a legal or moral or social duty of perfect or imperfect obligation and the person makes the statement, the statement is at least qualifiedly privileged. The Court states where the duty is a legal, moral or social, whether a perfect or imperfect obligation, the person is protected as a result of the privilege. I do not know whether the Court has read that authority recently, but in that case the facts were succinctly stated about as follows: An officer of a railroad company had reports as to the delinquency of an employee and in consequence a circular was issued, distributed not only to the employees of that railroad company but other railroads with reference to this man's inefficiency in his work, and the Court held that communication to be a qualified privileged communication, because there was a duty to protect the public. There was a public interest as well as a private interest at stake. In the second Federal Court decision which we cite, it appeared that other persons were present and heard it, heard the remarks. The Court in that instance said that the fact that some one else heard the remarks, that was incidentally present or were present where it happened in the course of a business transaction, it would not remove it from that realm. In the case of *Ashcroft v. Hammond*, 197 New York 488, also reported in 90 North-eastern 1117, suit brought against John Hays Hammond, in that particular instance while the telegram being libeling in its nature, yet the Court said the telegram was itself entitled to qualified privilege; that the fact the message was sent by telegraph and some other telegraph operators may have seen that telegram did not remove it from the realm of qualified privilege. That would be it of this telegram; it would not remove it from that realm and deprive the defendant from the protection. We have a number of cases which we can present to the Court dealing with this question and, if the Court would care to hear from us, we would like to read at least some of the decisions. While we have not the authorities direct at this time we do have memoranda of them, and in one or two instances full typewriter copy of the report. In one case which we have in mind it states that where malice or nonmalice would be equally strong from the message, the Court cannot presume a presumption of malice and therefore will not draw a conclusion where the malice or nonmalice may be coexisting. Those authorities we can present to the Court.

The Court:—The Court will hear from counsel for the plaintiff.

Mr. Quaid:—Your Honor, the first telegram which was introduced in evidence was to DeWitt Wallace asking him about what he thought about an article on the Brunson cure. The telegram from DeWitt Wallace to Dr. Fishbein asked him what he knew about the Brunson cure for the last twelve years, I believe that is the language of it—

Mr. Reynolds:—No, that is not it.

The Court:—Mr. Quaid, is that not set forth in the amended petition and in the answer?

Mr. Quaid:—The twelve years which was stated was in Mrs. Bradford's wire. Also she wired and asked what about the Brunson cure for twelve years, and DeWitt Wallace repeats that telegram to defendant Fishbein, which was in 1938. Now the pleadings show that we have notified Dr. Fishbein and the American Medical Association from time to time that Dr. Brunson was not using the Holderness formula and the defendant admits that they received that notice. That is in paragraph 4, "However, defendant admits the averment that a communication was addressed to him and to the American Medical Association of Chicago, Illinois, in writing advising this defendant that the plaintiff was not using the Holderness treatment but was using a medicinal formula and system of his own and that he requested an investigation with reference thereto." All right, then, in the telegram Dr. Fishbein sent, he said, "The Brunson cure of 1921," he admits at the time he sent that telegram, his pleadings admit at the time he sent that telegram he knew that Brunson was not using the treatment of 1921, because the investigation of 1921 made by Hruby was made on the Holderness treatment and was not on the Brunson treatment, so defendant Fishbein when he sent the wire connecting Brunson with the Holderness treatment, he knew, and now admits in this pleading that he knew, that at this time—knew, and now admits in this pleading that he knew, that at this time—he had received communications that we were not using that treatment and he had received investigation was made and the evidence in this case on which the Hruby investigation was used in 1921 and the first part shows that the Holderness treatment was used in 1921 and the first part of 1922 and Hruby made his investigation on the Holderness treatment. Now the defendant comes in and admits that he knows that Brunson was using the Brunson treatment and not using the Holderness treatment. I do think that goes very strongly to the question of qualified privilege. I do not agree with counsel about the law in this state on qualified privilege. In my reading some case decided some thirty or thirty-five years ago that

BRUNSON VS. FISHBEIN

137

judge suggested that Texas had not been very prolific on libel cases, he suggested that they had not been settled in Court. As you read the libel cases—and I believe I have read nine tenths of those in the last twenty-five years, probably not carefully, but when I saw a point applicable to our case I have read carefully—our courts have been a little lax, it seems to me in discussing the word "privilege." Whether it is an absolute privilege or a qualified privilege you have to read the case very carefully to see what the Court is talking about. As a matter of fact, qualified privilege is like any other fact, it is based on the facts of the case and it is not a naked question of law. An absolute privilege under our decisions, as I understand the loose language used, seems to be largely a question of fact and law. The question of qualified privilege is a mixed question of fact and law. I call the Court's attention to the record on that one fact, the submission. There is sufficient fact to go to the jury in this case on the question of qualified privilege. Now the case that seems to make the distinction on the question of privilege probably clearer than most of our cases is the case of Cobb v. Garlington, 193 S. W. 464. This is a case by the Court of Civil Appeals, Fort Worth, opinion by Judge Buck. This suit was brought for actual and exemplary damages based on a writing made by the City National Bank of Bowie, Texas, which was alleged to be libelous. The Court discusses privileged communication and qualified privilege, and the Court holds that the plaintiff in the case of qualified privilege still has the right to require that the alleged libel itself shall be submitted to the jury in order that they may pass on the question of whether there is evidence of malice on the face of the libel. Now the case of *Dickson v. Lights*, 170 S. W. 834, discusses there the question of malice and says that "Malice is question of fact and may be shown by extraneous facts and circumstances, or intrinsically by the violence of language used, the circumstances attending the publication, etc." *Behee v. Missouri Pacific*, 9 S. W. 449 says that "(a) Matter not relevant to the occasion may be evidence on question of malice. (b) Malice usually shown by extraneous evidence. (c) Animus may be shown by republication." As to being relevant, on this occasion he was asked about twelve years back, now he goes back eighteen years, although he admits in his pleadings he knew in the meantime that Brunson either claimed he was using another formula or he was using another formula and, so far as the evidence of this case is concerned, he was using another formula. In other words, I do not think Dr. Fishbein's telegram was entirely relevant to the occasion that was requested of him. I think that is clear that he disregarded the rights of the plaintiff and exercised an utter disregard of our rights in the matter, and, in fact, he admits in his pleadings that he knew we were not using the Holderness formula. At this time he admits Alheimer letter where this matter was again called to his attention and he still reiterates it is a dangerous form of practice or something to that effect. In other words, it is in the nature of a republication after it is called to his attention.

The Court:—Gentlemen, the counsel may prepare their motions in writing and file them and the Court will reserve ruling on the motion and we will proceed with the introduction of testimony in the case. The Court feels that a little light will be thrown on this case by future developments. Are you ready to proceed?

Mr. Brown:—Your Honor, it is difficult for us to proceed at this time without some ruling whether or not we can obtain that formula from Dr. Brunson.

The Court:—You may proceed just the same. You have the allegations in here. This has been analyzed and you have the result of the analysis, and that testimony may be brought in regardless of what you might have on the formula. The Court is reserving you the right to bring him back to the stand.

Mr. Harrell:—We are ready to proceed.

The jury then returned to the jury box and the following proceedings were had:

Mr. Harrell:—If the Court please, I have a deposition here of DeWitt Wallace, which I would like to read.

DEPOSITION OF DEWITT WALLACE.

The deposition of DeWitt Wallace, taken on the twenty-sixth day of April 1939, at 10 o'clock in the forenoon, before Hogarth S. Sweet, Notary Public, was then read in evidence as follows:

DIRECT EXAMINATION

By Mr. Harrell:—DeWitt Wallace stated that he lives at Mount Kisco, N. Y. He is editor of the *Reader's Digest* and was editor about January 1938. The *Reader's Digest* is a monthly magazine now in its eighteenth year of publication, reprinting material from magazines and books. It also contains original matter. Articles printed are in condensed form. A wide diversity of subjects are covered. "We try to find articles in at least twenty-five separate categories each month—sports, politics, literature, health, etc."

Q.—Are you acquainted with Mary Rose Bradford? A.—I've never met her but she is a close friend of Marquis James of Pleasantville, and a number of the associate editors are acquainted with her.

Q.—Do you know what she does or did on or about January 1938? A.—She sent us a telegram asking whether we would be interested in an article about Dr. Asa Brunson of El Paso. Presumably she is a writer. Her husband, of course, has a great reputation and, no doubt, she has written herself. Personally, I am not as well acquainted as I should be with what she has written.

Q.—Now you say that Mary Rose Bradford sent you a telegram in January 1938. I'll ask you, Mr. Wallace, if this is the telegram that you received from Mary Rose Bradford? A.—Yes, that is a copy.

THE TELEGRAM FROM MARY ROSE BRADFORD

DeWitt Wallace, Reader's Digest, Pleasantville, N. Y. Are you interested in article about Dr. Asa Brunson of El Paso, who has been making quiet but remarkable cures in pulmonary tuberculosis with formula used in atomizer or nebulizer and sprayed into lung by inhalation? Three thousand cures in twelve years. American Medical Association refuses to investigate, but patients are flocking to El Paso to be cured within six months. Dr. Brunson has begged United States Surgeon General for hundred patients for simultaneous treatment with hundred treated in usual way with monthly examination but no go. Brunson is licensed M.D. and comes from a long line of American physicians. He may be another Pasteur and a prophet without honor. We are here for couple weeks; spent Xmas in Santa Fe. Wire me Hotel Del Norte.

Mary Rose Bradford

Q.—Now on receiving this telegram did you take any action, Mr. Wallace, regarding the suggestion in the telegram regarding writing an article about Brunson's alleged tuberculosis cure? A.—Yes.

Q.—What did you do? A.—I sent Dr. Morris Fishbein a telegram asking for his opinion about this so-called cure, quoted from the telegram sent to us by Mary Rose Bradford.

Q.—I show you, Mr. Wallace, a telegram addressed to Dr. Morris Fishbein, signed DeWitt Wallace, *Reader's Digest*, which has been marked "Defendant's Exhibit III." Is that the telegram? A.—Yes, sir.

Mr. Harrell:—I offer it in evidence and ask to read it in evidence:

Received at
NB577 110 NL XC-TDWS
Dr. Morris Fishbein
American Medical Assn., Chicago, Ill.

WESTERN UNION
1938 Jan 19 PM 10 25
MTKISCO NY 19

Please advise wire collect or air mail what you think of the following statement: "Dr. Asa Brunson of El Paso, Texas, has been making quiet but remarkable cures of pulmonary tuberculosis with formula used in atomizer or nebulizer and sprayed into lungs by inhalation. Three thousand cures in twelve years. Patients are flocking to El Paso to be cured within six months. Dr. Brunson has begged U. S. Surgeon General for hundred patients for simultaneous treatment with hundred treated in usual way with monthly examination but no go. Brunson is licensed M.D. and comes from a long line of American physicians. He may be another Pasteur and a prophet without honor."

DeWitt Wallace, Reader's Digest

Q.—Now, Mr. Wallace, did you receive any response to your telegram to Dr. Fishbein? A.—Yes, we received a telegram dated January 20, 1938.

Q.—Now, Mr. Wallace, I show you a telegram addressed to yourself from Morris Fishbein, which has been marked "Defendant's Exhibit IV" and ask you if that is the telegram that you received. A.—Yes, that is the telegram.

WESTERN UNION
PHF 4 TWS COLLECT CHICAGO, ILLINOIS, JANUARY 20, 1938

Mr. DeWitt Wallace,
Reader's Digest—
In ans your NB 577 110 NL XC-TDWS
Mt. Kisco, New York—
Brunson cure investigated by Allen Hruby, medical superintendent Chicago Municipal Tuberculosis Sanitarium. He says treatment without value as specific or cure for consumption. In my opinion it is a fake of the most dangerous kind. Treatment involves inhalation of menthol, eucalyptol and turpentine. Similar methods tested elsewhere have also proved to be failures.

Morris Fishbein.

Q.—Now, on receiving defendant's Exhibit IV from Dr. Fishbein, did you take any action or do anything in regard to printing the article suggested by Mary Rose Bradford? A.—I sent a telegram to Mary Rose Bradford quoting from Dr. Fishbein's telegram, indicating that we would not be interested in such an article.

Q.—Is this the telegram you have reference to, Mr. Wallace? A.—Yes, that is the telegram.

COPY POSTAL TELEGRAPH

Mary Rose Bradford,
Hotel Del Norte, El Paso, Texas, January 25, 1938.

Fishbein of American Medical Association wires: Brunson cure investigated 1921 by Allen Hruby, medical superintendent Chicago Municipal Tuberculosis Sanatorium. He says "Treatment without value as specific or cure for consumption. In my opinion it is a fake of the most dangerous kind." Treatment involves inhalation of menthol, eucalyptol and turpentine. Similar methods tested elsewhere have also proved to be failures.

DeWitt Wallace

Q.—Now, did you have any further or other correspondence or telegrams with Mrs. Bradford in regard to this alleged tuberculosis cure? A.—Yes, I believe we had a letter acknowledging my telegram from Mary Rose Bradford.

Q.—I show you, Mr. Wallace, what purports to be a letter from Mary Rose Bradford to you dated Jan. 27, 1938, which has been marked "Defendant's Exhibit VI" and ask you is that the letter that you received from Mrs. Bradford? A.—Yes, that is the letter.

Mr. Harrell:—I offer in evidence defendant's Exhibit VI:

The letter follows:

Hotel Paso Del Norte

Jan. 27, 1938.

Dear Mr. Wallace:

Thank you for your wire about the Brunson T. B. cure. I was interested only from the journalistic viewpoint, naturally. I turned the wire over to Dr. Brunson, as it seemed more eloquent than anything I could say.

You'll had better follow the Achesons to New Orleans—they liked it. Our address there is 719 Toulouse St. Phone (unlisted) is Raymond 6635.

Faithfully,

Mary Rose Bradford.

Q.—Did you have any other correspondence with Mrs. Bradford regarding her suggestion that you print this article? A.—Not that I recall.

Q.—Now, prior to receiving the telegram from Mrs. Bradford, had you ever heard of a doctor by the name of Asa Brunson? A.—No, I had never heard of Dr. Brunson.

Q.—Had you ever heard of any doctor having made a remarkable discovery for the cure of tuberculosis? A.—No, sir. Not to my recollection.

Q.—What was your reaction, Mr. Wallace, regarding this article when you received the telegram from Mrs. Bradford? What I want to know is how you felt with her about printing such an article? A.—My feeling was one of complete skepticism.

Q.—What do you mean by that?

Mr. Quaid:—Just a moment. Let's see the answer. Your Honor, I am going to object to that answer as not material to anything.

The Court:—Let me see the answer.

Mr. Quaid:—It is his own reaction about a cure he had heard of, and all of that; it is immaterial and irrelevant and has no bearing on the issues in this case.

The Court:—The Court sustains the exception.

Mr. Harrell:—Note an exception, Your Honor.

The Court:—Under the new rules you don't have to do that. Under the new rules you are spared that trouble. The Court will, in explanation of the Court's ruling, why the Court overrules (sustains) it, in order we may have a clear understanding it is but a dissertation by this gentleman repeating what others may have said perhaps to him, or inferences he drew from others, and has no legal bearing on this case at all, and the Court sustains the exception, as immaterial.

The answer was not admitted or read.

Q.—Mr. Wallace, was your action in reference to the suggestion of Mrs. Bradford, that is, after you received her telegram, any different from that of any other similar suggestion regarding a scientific question? A.—No, none whatever.

Q.—What I want to know is did you depart from your usual course of investigation in this particular instance by making your inquiry of Dr. Fishbein? A.—Yes, and for this reason. We have some thirty-five people on our editorial staff, all of whom are supposed to make suggestions from time to time for original articles. In times past when they have suggested an article on some medical subject based on a newspaper item it has been an easy matter to explain our attitude to them personally. We also receive a good many unsolicited manuscripts from people of no established reputation, and we have no hesitancy in returning such manuscripts with our usual rejection slip; but, because of the personal relationship with Mary Rose Bradford, and because of her reputation and that of her husband, we were interested in not appearing to be arbitrary in our decision and felt it would be courteous to go to a medical authority for his opinion on her suggestion. That is the reason why in this case we sent a telegram to Dr. Fishbein.

Q.—Did you handle this matter personally, Mr. Wallace? A.—Yes, I did.

Q.—That is, you received Mrs. Bradford's telegram, and then you, in turn, made inquiry by wire of Dr. Fishbein, and then received his reply. Is that right? A.—Yes, I handled the matter personally.

Q.—Do you receive many suggestions for the publishing of medical articles in the *Reader's Digest*? A.—Not so many as formerly from our own staff because they have come to know our attitude about such articles, particularly in cases involving a so-called remarkable cure of some sort.

Q.—Before you made inquiry of Dr. Fishbein regarding this cure, was it or was it not your intention to print this article in the *Reader's Digest*?

Mr. Quaid:—Just a moment. Let me see that. Your Honor, I object to it because it is asking for a conclusion, and what he would do. The question is "Before you made inquiry of Dr. Fishbein regarding this cure, was it or was it not your intention to print this article in the *Reader's Digest*?" He does not answer it yes or no. He rambles off here.

The Court:—Let me see it.

Mr. Harrell:—He gives his reasons, Your Honor, and that is one of the main reasons in this case on which they predicate damages, the failure to print the article.

The Court:—It is predicated on a telegram. The Court will overrule the exception.

Mr. Quaid:—Note our exception.

A.—Actually, we had no serious intention of availing ourselves of the suggestion from Mrs. Bradford. As I said before, I was not impressed with Mrs. Bradford as an expert in this particular field, and our whole policy has been to avoid a subject of this kind. I refer, of course, to the development of an original article. We print articles, of course, about various cures. There are, of course, writers who have established reputations as writers on medical themes.

CROSS INTERROGATORIES AND ANSWERS THERETO
INTRODUCED BY PLAINTIFF

The witness again identified the telegrams.

Cross Interrogatory No. 5:—State whether or not you obtained from THE A. M. A. JOURNAL, from *Hygeia* or any other publication of Dr. Fishbein's any intimation or statement with reference to Dr. Brunson, his tubercular treatment, or touching on his individual character, responsibility or reputation. Answer fully. A.—We have made no further investigation of the subject at all after receiving the telegram from Dr. Fishbein.

Cross Interrogatory No. 6:—State whether or not, after receiving information from Dr. Fishbein with reference to Dr. Brunson or Dr. Brunson's tubercular treatment, you formed from such information an opinion causing you to be prejudiced against Dr. Brunson. A.—Dr. Fishbein confirmed the feeling we already had that it was not the type of article which we cared to undertake as an original article for the *Reader's Digest*.

Cross Interrogatory No. 7:—State whether or not you had intended to publish the story to be written by Mary Rose Bradford about Dr. Brunson. A.—We had no such intention and, as I have already said, we wired Dr. Fishbein only as a courteous procedure in response to the suggestion from Mrs. Bradford.

Cross Interrogatory No. 8:—State why, or on whose suggestion or advice, you communicated with Dr. Fishbein. A.—I communicated with Dr. Fishbein wholly on my own initiative in the belief that he might have some information in his files pertaining to Dr. Brunson.

Cross Interrogatory No. 9:—State whether you were personally acquainted with Dr. Fishbein and any of the officers, agents, attorneys, or representatives of the A. M. A., stating the extent of your acquaintance and what relationship, in a business way, if any, exists between you. A.—In January 1938 I had never seen nor met Dr. Fishbein, nor any of his attorneys and, so far as I know, had never met any person from his office in Chicago or connected with the American Medical Association. Since that time I have met Dr. Fishbein in connection with an article or two that we were considering.

Cross Interrogatory No. 10:—It is a fact, is it not, that you intended to publish a story written by Mary Rose Bradford about Dr. Brunson and would have done so had it not been for information and representations from Dr. Fishbein. A.—There is no truth whatever in this statement. We were not at all impressed with the suggestion when it was first received from Mrs. Bradford.

Cross Interrogatory No. 11:—If you answer the foregoing in the negative, then state why, if you did not intend to publish such a story, did you take the matter up with Dr. Fishbein. A.—The matter has been touched on already once or twice. The

fact of the matter is that we wanted to "pass the buck" to some one else, and if it hadn't been Dr. Fishbein it probably would have been the Academy of Medicine in New York City.

Cross Interrogatory No. 12:—Do you rely on Dr. Fishbein in reference to any matter pertaining to doctors or medicine that you may comment on in the *Reader's Digest*? *A.*—We, as I have said, check our articles very carefully but generally find experts on any given subject closer at hand. Our associate editor, Henry Morton Robinson, handles most of our medical articles, and he has a wide acquaintance among the medical fraternity here in the East and usually checks medical material with authorities in New York City or at Johns Hopkins or in Philadelphia or Boston.

Cross Interrogatory No. 13:—Do you, in the *Reader's Digest*, only comment on physicians or medicine, or medical matters, which receive the approbation of Dr. Fishbein, or are you independent and give publicity to such matters, irrespective of Dr. Fishbein's opinion, that you believe will be informative or interesting to your readers and the general public? *A.*—We constantly reprint medical articles from other leading magazines, and in no case that I can recall have we questioned the validity of an article appearing in *Collier's*, or the *American Magazine*, or the *Saturday Evening Post* by questioning Dr. Fishbein.

Cross Interrogatory No. 14:—Do you depend on Dr. Fishbein and allow him to censure matters appearing in the *Reader's Digest* pertaining to medicine, physicians or health? *A.*—There has been no censure whatever, as has been made abundantly clear in the preceding testimony. This is the only case that I recall in which we have passed on a suggestion from an original article to Dr. Fishbein respecting a specific cure.

Cross Interrogatory No. 15:—Do you reject for publication any matter of general interest pertaining to doctors, medicine or medical treatment because of your fear of the Medical Association and the reaction it would have against your publication? *A.*—We pride ourselves on being a little more fearless than any other magazine published. A scrutiny of the *Reader's Digest* in past years will provide the best answer to that question, in that we have published numerous articles which have antagonized members of the medical profession and the American Medical Association.

Cross Interrogatory No. 16:—Do you fear resentment from the Medical Association in commenting on medicine, doctors or medical treatment? *A.*—Positively no.

Cross Interrogatory No. 17:—Is it not a fact that you were advised that the treatment being offered by Dr. Brunson had never been investigated by the A. M. A. or Dr. Fishbein but that his treatment was inaugurated and offered to the public long after any purported treatment or investigation thereof in 1921? Attach hereto any communication that you may have had so advising you, or the substance of any conversations that you had in reference to being notified that the treatment had not been investigated by any authority whatsoever. *A.*—I recall having received a letter later from Dr. Brunson in which he made the claim that the A. M. A. had never investigated his cure and I believe I can produce such a letter from our files; but this letter did not in any way alter our general attitude toward publishing medical articles making sensational claims of cures of diseases of this sort.

Cross Interrogatory No. 18:—Did you anticipate incurring the displeasure of Dr. Fishbein, or the A. M. A. by reason of any comment that you might have made favorable to Dr. Brunson? *A.*—I never gave the matter a thought.

Cross Interrogatory No. 19:—Attach hereto and mark for identification any communications that you may have received from any source whatsoever approving the Brunson treatment. *A.*—As I recall, Dr. Brunson did enclose a number of testimonials from certain people regarding this so-called cure, but I did not read the letters very carefully because, as I have already said, the general subject did not interest us. These letters were returned to Dr. Brunson with a courteous letter of transmittal.

Cross Interrogatory No. 20:—Had you not received a telegram from Dr. Fishbein condemning the Brunson treatment, you would then have published the Bradford story, would you not? *A.*—Positively no.

Cross Interrogatory No. 21:—If you state you would not, give your reasons, and if your mind had been made up, why the precaution of communicating with Dr. Fishbein?

Mr. Quaid:—You objected to that.

Mr. Harrell:—I submit the question has already been asked, Your Honor, and has already been answered, the same question.

The Court:—This is on cross examination. I will overrule the exception.

A.—To try to answer this question in a different way, having already answered it several times, I might explain again that

medical articles in the best magazines are fairly frequent. The only purpose of developing original articles ourselves is to supply us with material in certain categories of subject matter which enable us to give the widest possible diversification of content in each issue. There is no precedent for our having developed an original article pertaining to any sensational cure with the possible exception of an article which we printed on a preparation which covered facial blemishes. This article appeared a number of years ago and the preparation is called "Covermark." Neither before the receipt of Dr. Fishbein's or Mrs. Bradford's telegram, nor since, have we given any serious consideration to an article pertaining to a sensational cure claimed to be developed by some individual doctor. There simply is no necessity whatever for us to develop original medical articles of this caliber.

RE-DIRECT EXAMINATION

By Mr. Harrell:

Q.—You don't as a rule publish articles containing sensational claims of cures in the *Reader's Digest*, do you Mr. Wallace? *A.*—If we do, we reprint them from other leading magazines and do not originate the articles ourselves.

Q.—Well, of course, you are interested in keeping your magazine on a high plane? *A.*—Decidedly.

Q.—You spoke of having printed a medical article several years ago regarding face cream. You published that in the *Reader's Digest*? *A.*—Yes, we had a contest soliciting original articles—

Mr. Quaid:—The balance is not responsive, the yes is all right, he starts on about a contest or something that caused him to publish it, I think that is immaterial and irrelevant. When he says yes, he answers the question, that is all right, he goes on about a contest.

Mr. Harrell:—He explains the circumstances after the response yes.

Mr. Quaid:—It does not need any explanation.

The Court:—Overrule the objection.

Mr. Quaid:—Note our exception.

A.—Yes, we had a contest soliciting original articles from people who have never written for leading magazines before and we received a total of 48,000 manuscripts. This was one of ten or twelve articles which we finally printed out of this contest, and it concerned a preparation to cover birthmarks and facial blemishes.

Q.—Well, that would be under the general heading of cosmetics? *A.*—Yes, decidedly. In that case, I went down with my wife, saw the woman in her office, saw her apply the preparation, and we employed a first-rate investigator to spend some two or three weeks further investigating those who had made use of the preparation, getting first-hand information as to the accuracy of any claims which she made for it.

Mr. Quaid:—After the word yes, it is all irrelevant and incompetent.

The Court:—Sustain the objection.

Q.—Did you publish Dr. Fishbein's telegram regarding Brunson's T. B. treatment to any one? *A.*—We quoted from it in our telegram to Mrs. Bradford.

Q.—Did you publish it to any one other than Mrs. Bradford? *A.*—No, certainly not, we had no occasion to refer to the matter again.

Q.—So, in so far as you know, the only persons who have knowledge of Dr. Fishbein's telegram are yourself, your secretary and Mrs. Bradford. Is that right? *A.*—Yes. I did not consider the matter important enough to discuss with any associate editors.

Q.—Well, you didn't give any publicity to what was contained in the telegram to any one? *A.*—Certainly not.

Thereupon court recessed, at 5 p. m., to reconvene at 9:30 a. m. Wednesday, May 31.

Wednesday, May 31

TESTIMONY OF DR. ALLEN JOSEPH HRUBY: ON DIRECT EXAMINATION

Questions by Mr. Harrell:

Dr. Allen Joseph Hruby stated that he lives in Chicago. He attended the University of Illinois, 1909-1913, receiving the degree of doctor of medicine. After graduating from the University of Illinois by competitive examination he was admitted as intern to the Cook County Hospital, serving from June 1913 to March 1915. He then had one year of research at Wesley Hospital, Chicago, connected with Northwestern University, and one year as a public health school officer. Next, while still connected with the health department, he took a competitive examination for the dispensary service of the Chicago Municipal Tuberculosis Sanitarium and was appointed by civil service

examination in July 1917, serving from July 1917 to July 1918, when he had an appointment as medical superintendent of that institution. As school health officer for the city of Chicago, 1916-1917, he examined school children and made general surveys in the various rooms, grades and rooms, investigating every absentee. As dispensary physician for the Municipal Tuberculosis Sanitarium he did physical examinations of patients from 9 in the morning until 5 in the evening, with one hour off at noon, every day, half a day Saturday, for one year. The average was at least thirty or forty patients a day.

Q.—How many patients on an average were there in the Chicago Municipal Tuberculosis Sanitarium during the time you were dispensary physician, if you know? A.—In those years the population ran from about 700 to 800.

Q.—As medical superintendent of the Chicago Municipal Tuberculosis Sanitarium, what did you do in that capacity? Tell us in a general way what your duties were. A.—Work of a superintendent, supervisory, with a senior physician under me and about eight junior physicians, making the rounds once, sometimes twice, a day, holding conferences and consulting on every difficult case in that institution, and that from 1918 to 1923, five years.

Q.—Now, by holding conferences, just what do you mean, Doctor? A.—The discussions on the diagnosis and treatment of the individual cases, and particularly those that presented difficulties.

Q.—And for how long a time did you hold that position as superintendent of the Municipal Tuberculosis Sanitarium? A.—From July 1918 until about December 1922, almost to 1923; in fact, I was there as an honorary man to induct the next man into the job.

Q.—Approximately how many persons afflicted with tuberculosis were in the sanatorium during those times; that is, about the date July 1918 to 1923? A.—About 700 to 800, sir.

Q.—During that course of time did you attend any post-mortems, Doctor? A.—Yes, sir.

Q.—About how many would you say? A.—That is pretty hard to say.

Q.—Well, can you give us an estimate of how many, a large number or small number? A.—Well, you see in a tuberculosis sanatorium we don't have the number of "posts" we have in a general hospital, but I would say I had at least twenty-five "posts"—fifty "posts," twenty-five to fifty.

Q.—You wouldn't know about how many? A.—But it is not much there, no.

Q.—Now, after you left there in 1923, that is, you left your position as superintendent of the sanatorium, then what did you do? A.—After I left the sanatorium I did general chest work in private practice.

Q.—What do you mean by chest work? A.—Not only tuberculosis but diseases of the chest, heart and lungs.

Q.—Now, that was when, between what dates? A.—1923 until 1931. I was not connected with any institution whatever.

Q.—Now, in 1931 were you appointed to any position with the same institution, the Municipal Tuberculosis Sanitarium? A.—By the mayor of the city of Chicago I was appointed in the spring of 1931 to serve as a member of the board of directors of the Chicago Municipal Tuberculosis Sanitarium.

Q.—Do you hold any other position besides being a member of the board of directors of that institution? A.—Yes, sir, I do.

Q.—What is that? A.—By civil service examination I received my appointment to the Cook County Hospital, where I am today an attending man in the tuberculosis department of that institution.

Q.—How large is the tuberculosis ward in the Cook County Hospital? A.—We have 350 beds there, sir.

He testified he is also on the staffs of Washington Boulevard Hospital, the Saint Anthony Hospital and medical consultant for the C. M., St. P. & P. Railroad. He also listed his membership in various medical societies or associations.

Q.—Now, Doctor, aside from your research work and experience in the Chicago Municipal Tuberculosis Sanitarium and your experiences at the Cook County Hospital, have you attended any clinics or postmortems having to do with tuberculosis anywhere else? A.—From 1932 to date, almost every week, I attend what we call at the Cook County Hospital the pathology conferences, held, until his death, by Professor Jaffé, and since his death by Professor Schiller. In those conferences we have viewed from four to five dead bodies each week since 1932.

Q.—Those persons died of what diseases? A.—Of all general diseases, surgical, medical, tuberculosis and everything.

Q.—Have you attended any foreign clinics, Doctor? A.—Yes, sir. In 1932 I studied with Professor Tice the proposition of vaccination in children against tuberculosis, and Dr. Calmette, at the Pasteur Institute, where we developed a culture from that laboratory, by sending another physician to study one year and bring the culture across the ocean, and where we are continuing vaccination of newborn infants for prevention of tuberculosis.

Q.—That was the Pasteur Institute in Paris? A.—Yes, sir, Paris, France.

Q.—Who is Professor Tice? A.—Professor Tice is the president of the board of directors of the Chicago Municipal Tuberculosis Sanitarium, and I am his secretary and a member of the board as well.

Q.—Have you made any other studies in other countries than in the United States on tuberculosis? A.—No, sir, just that have attended the international conferences at The Hague Netherlands, in 1932.

Q.—Did that have reference to tuberculosis? A.—Yes, sir.

Q.—Doctor, I show you part 6 of page 5 of the *Chicago Herald and Examiner* for Sunday, Sept. 4, 1921, and call your attention to an article headed "Dr. Hruby calls tuberculosis curable a fake of most dangerous kind," and I will ask you if you have seen that before? A.—I did, sir.

Q.—Is that an article that was written after you had been in El Paso and investigated the Brunson-Holderness remedy?

Mr. Quaid:—I want to object to that. First, the Holderness remedy is not in issue in this case. The telegram of Dr. Fishbein refers to the Brunson cure of 1921, and this is not in issue in this case, what he may have found or said about the Holderness cure at that time.

The Court:—That could be true, unless it is connected up by counsel.

Mr. Harrell:—We have set this out in our answer; I think we attach a copy in our answer. Of course, it wasn't in newspaper form but typewritten form; it was taken from the newspaper article.

The Court:—The newspaper feature hasn't anything to do with its admissibility unless you connect it up.

Mr. Harrell:—We will connect it up.

The Court:—How do you expect to connect it up?

Mr. Harrell:—I expect to connect it up by the testimony of Dr. Fishbein, that he obtained his information from this report, part of the information which he used in the telegram to DeWitt Wallace.

The Court:—The report is referred to in the telegram of January 1938. The Court will permit, in view of that fact, inquiry into many features in this case, various and sundry damages, good faith, and so forth. Overrule the objection with the assurance of counsel that it will be connected up, that report to which reference is made.

A.—Yes, sir.

Q.—Now, Doctor, I notice this article, at the heading, says by Allen J. Hruby, M.D. I will ask you if you personally wrote this article? A.—I wrote the reports of the patients and investigations here and submitted that report, from which that article was written.

Mr. Quaid:—We further object then the article wasn't written by him.

The Court:—Gentlemen, you have got a charge in here that some one's reputation has been injured maliciously; this telegram seems to be pertinent. Counsel has stated, and the Court relies on the assurance of counsel that counsel will connect it up, that he saw this article and read this article. In connection with that further investigation he made, he refers to the report of Dr. Hruby, which is mentioned in the telegram which is the basis of your action.

Mr. Quaid:—We would like to make the further objection that the newspaper article is not the report of Dr. Hruby.

The Court:—The Court overrules the objection.

Mr. Quaid:—We except.

Q.—Did you make an investigation of the Brunson-Holderness treatment for tuberculosis? A.—Holderness-Brunson, yes.

Q.—When? A.—Between sometime in July and August 1921.

Q.—Where did you conduct that investigation? A.—At the Holderness-Brunson Clinic and in the homes of patients.

Q.—Now, Doctor, will you tell us in your own words just what you did in conducting that investigation?

Mr. Quaid:—If the Court please, I do not want to be objecting all along. I would like to have it understood my objection goes to all this testimony.

The Court:—This is a different question. The Court will call your attention to the fact that in examination, in direct, witness Brunson, the plaintiff of this suit, was asked questions and inquiry elicited as to Dr. Hruby coming to El Paso and making some character of investigation. Overruled. The Court will say it is not necessary to note the exceptions. Under the rule, if you make an exception, if the ruling is adverse to you the rule provides you have an exception.

A.—Examining patients physically, taking histories first and trying to find out what laboratory work had been done. After

I completed the history and examination and got reports on laboratory work I was able to do it myself. I did that at the clinic and at the homes.

Q.—Tell us where was the first place you went to after coming to El Paso. A.—The first place I went to was the Holderness-Brunson Clinic.

Q.—Whom did you meet there? A.—Dr. Holderness, I believe.

Q.—Where was that clinic located, if you recall? A.—I do not recall.

Q.—After arriving at the clinic what did you do? A.—I introduced myself to Dr. Holderness, stated that I was a physician from Chicago, connected with the Chicago Municipal Tuberculosis Sanitarium, and that we, in Chicago, were very much interested in the cure, if he would be kind enough to show me the methods of treatment and what the treatment consisted of and the cures he claimed he had in the papers, or copies of the papers that were coming up to our papers in Chicago.

Q.—Did you meet Dr. Brunson? A.—I think I did.

Q.—Did you examine any patients at the clinic, Brunson-Holderness Clinic? A.—I did, sir.

Q.—How many did you examine there? A.—About a half a dozen in round numbers.

Q.—How long did you remain at that clinic? A.—I think a good part of the morning.

Q.—Where did you go from the clinic? A.—Probably to lunch and then, after lunch, started my rounds to the home addresses that were given to me by the clinic for me to examine and investigate.

Q.—Do you recall what patients, that is, outside patients you examined? A.—Yes.

Q.—Will you name them please? A.—Could I refer to my notes?

Q.—Yes, you can refer to your notes but you cannot read from the notes. You can refresh your memory. Now, Doctor, before referring to your notes just tell us what those notes are. A.—The notes are the original notes that were actually taken in the clinic and at the bedside; they are getting yellow with age, so hard to read I just recopied them so they would be more plain in evidence.

Q.—Those you hold in the right hand are the original notes? A.—The original notes taken here in El Paso eighteen years ago.

Q.—Go ahead and name the patients. A.—Griffin, McLean, McLeod—

Q.—Give us the full names if you have them. A.—I have not. McLeod, that is Mrs. McLeod, Mr. Martin, Mrs. Rachels.

Q.—We will now take them one at a time. Let us take Griffin. A.—May I take a few moments to read this?

Q.—Yes. A.—Yes, sir.

Q.—Now tell us what you did in examining Mr. Griffin, what you found. A.—Took a history and did a complete physical examination.

Q.—Describe what you did. A.—In the history he was a man aged 40, he had been sick since he was the age of 33 and had asthmatic attacks since childhood. He had influenza-like exacerbation once or twice a year.

Q.—What do you mean by exacerbation? A.—That means he was going along all right, not feeling too well, but every spring and fall he would have an attack of influenza. Then he finally heard he had tuberculosis prior to the time he came to the Holderness-Brunson Clinic. He blamed his contraction of tuberculosis on being in contact at the same desk with three tuberculous men, and that was what he thought caused his tuberculosis, this contact with three tuberculous men working at the same desk. I believe that desk was a desk in a newspaper firm in San Francisco. Then he said that the last time he was sick was about for two months and would not let up until he got very bad and then he went to the Holderness-Brunson Clinic and he stated that he took one treatment and after that immediately got better. He was up in three days and about in one week of treatment and the nurse found his pulse and temperature normal. On my visit to him I had taken his temperature and found it normal. I found his pulse to be 88 and his blood pressure, however, very low. It measured at that time 98 systolic and 62 diastolic. Now, he was a middle aged man, about 5 feet 5 inches tall. He was very thin and emaciated, pallor, cyanotic lips, wide palpebral fissures, and what we call a tuberculous stare.

Q.—What do you mean by palpebral fissures? A.—That is due to the atrophy of the palpebral muscles that controls our

wink or our winks. That becomes atrophied in long chronic cases.

Q.—Doctor, when you use those terms, will you explain them. Neither the jurors nor we are medical men. A.—It is the wasting of the muscles in tuberculosis around the eyes and causing a widening of the palpebral fissure and the side most involved will give the greatest width. In this case it was on the left side, the left palpebral fissure. He was of brunet complexion, large brown eyes and the muscles of his neck stood out prominently and there was a wasting of his neck and he was very short of breath, with blue lips, and he coughed considerably and the cough was very productive. He was throwing it out of him, not only what I saw when I was examining it but what he told me. He talked jerkily, he was all out of breath and that made me suspect he might have fluid even before I examined the chest. When you have fluid in the chest your patient will talk jerkily. He had rales, sentinels of moisture in his chest on both sides and very active tuberculous pathology. He had dulness over both upper lobes denoting an old fibrotic tuberculosis in these parts. I made the diagnosis of an old chronic fibroid pulmonary tuberculosis without any laboratory notes from the clinic or without an x-ray and that this old fibroid pulmonary tuberculosis of the asthmatic type was of very long standing before he came to this clinic. Now, the mental tendency of the man was typical of tuberculosis, a very hopeful psychology, and he said he had most excellent results from his treatment, but that was his subjective statement to me as how fine he felt, but on examination I found very active pulmonary tuberculosis and I was surprised that I did not see the first cure.

Q.—Where was he at the time you conducted this examination? A.—This was at his home, I believe.

Q.—Now, Doctor, will you take the next patient you saw—first, who was she or he? A.—Mr. McLain.

Q.—Who was Mr. McLain? A.—He was a patient of the Holderness-Brunson Clinic and I saw him, I believe, at his home also.

Q.—Will you tell us what you did on examination of Mr. McLain? A.—Mr. McLain first gave us the history.

Q.—First give us the history if you want to and tell us of the examination. A.—In taking his history Mr. McLain was 40 years of age, and he too had been sick for some years, just like the previous case, forty or more and all of long standing illness before they presented themselves for treatment. He was diagnosed as bronchitis, had frequent and protracted colds, pain in his chest and was spitting blood and he lost a lot of weight. The temperature at the time of my examination was 99.5, about a degree higher than normal, pulse 110, rather rapid, the blood pressure 110 systolic and 70 diastolic. Dark complexion, about 5 feet 6 inches tall, very thin, cadaverous, very emaciated like a case of pulmonary tuberculosis far advanced. He was extremely nervous and he had a positive sputum. That report was given me by the Holderness-Brunson Clinic and it was still positive when I examined him. He had moist rales in both lungs, that is, bubbling, like the frying of potatoes on a frying pan, bubbling all over his chest, with dulness all over but mostly in the apices and all this denoting activity and this after twenty-five treatments, and he was still running a temperature as high as 100 degrees. I made a diagnosis of acute exacerbation of a chronic fibroid ulcerative pulmonary tuberculosis. You will ask how I could make that without an x-ray plate. By physical examination; but mainly there had been a fracture of the continuity of the tissues of the lung that caused that hemorrhage. You cannot have a hemorrhage without a fracture of the tissues. That was caused evidently by cavitation in the lung. His mental condition—he thought he must do something for his paper, so running this big story.

Q.—Was he a newspaper reporter also? A.—Yes, sir.

Q.—Who is the third patient you examined? A.—Mrs. McLeod. I do not know they were in this sequence.

Q.—Where was she when you examined her? A.—In her home.

Q.—When you say in their homes you mean in their homes here in El Paso? A.—Yes, sir.

Q.—Will you tell us what history you got from Mrs. McLeod and then relate your examination? A.—Mrs. McLeod was a woman aged 30. She was fair complected, blue eyes, but very thin and emaciated and when I saw her she was confined to bed. Claims to have been sick for a long time before she saw the clinic of Holderness-Brunson. She was sick for four years, and I think that is one of the youngest cases I examined. Most of them ranged from 35 to 60 years of age, and that is when we get a certain type of pulmonary tuberculosis.

Q.—How old was Mrs. McLeod? A.—Thirty. Last April she began the Holderness treatment and had taken it for two months and one week when I saw her. The treatments first increased her sputum but she now coughs less and expectorates lightly. She told me this. This was not the report of the clinic. Her last three sputum examinations were negative. I asked the clinic how they examined their sputum. They reported just the ordinary smear and Ziehl-Nielsen stain, but just by the ordinary smear and not by any concentration cultures or guinea pig inoculations. She refused to be examined by me. She refused to be examined by me or even have her temperature taken by me, so I have no physical examination to report in this case but only what I saw and that was that she was still too weak and too sick to be up.

Q.—What was the name of the next patient you examined? A.—Mrs. Dunn.

Q.—Where was Mrs. Dunn when you examined her? A.—At home.

Q.—Here in El Paso, is that right? A.—Yes.

Q.—All right, tell us about Mrs. Dunn. A.—She was a woman aged 40 years, and she too was sick for a long time, for five years, and she was taking treatment from the Holderness-Brunson Clinic for seven weeks. Her sickness started with hemorrhage and when a sickness starts with hemorrhage we should always consider it tuberculosis unless we can definitely prove that it is not so. I found her temperature to be normal and she said that her sputum disappeared and was negative for three weeks, but not by any report from the clinic or clinical report from that laboratory—just by her statement. She had been up and about and working as a housewife. Slender, tall woman with a hoarse voice, husky voice, which is characteristic in tuberculosis and that huskiness in the voice may be either due to paresis or weakening of the vocal cords or may be due to an ulceration of those cords. She, however, had no complaint of pain in her throat and when we have ulceration in the throat the pain is terrific, so much so they cannot swallow water, so I figured it not a tuberculous ulceration of the throat or epiglottis or thyroid cartilage but of extreme weakness. She was a tall woman. No examination allowed, however, but my impression with the meager things that were given me was that she had a chronic fibroid tuberculosis ulcerative and again ulcerative because of the hemorrhage at the onset.

Q.—What was the next patient you examined? A.—I called on several on my list, Mrs. Cannon, Mrs. Jerrigan, Mrs. Cannon, not at home, Mrs. Jerrigan, not at home, and I made an attempt to get there again but I could not find them. Mrs. Dora Rachels was not at home but I made a second call there.

Q.—Did you see Mrs. Rachels? A.—Yes, sir.

Q.—Did you get Mrs. Rachels' history and examine her? A.—Yes.

Q.—All right, tell us about Mrs. Rachels. A.—Mrs. Rachels was a woman age again of 40; her onset of her illness was again by hemorrhage. Her findings were very meager. Now this is eighteen years ago and I state here "She presented dry sibilant rales in both apices." Now, what do I mean by dry sibilant rales? They are caused by a sticky mucus in the very fine tubes of the lung and when the patient breathes it is like a whistle, it is like a reed in a tube, it whistles, and they were not—or they were very meager too. Findings were not marked but those were the findings of my physical examination without the aid, again, I will say of x-ray, blood work and sputum work, but because of these few rales I found in the apices of her lungs and because of the hemorrhage that she said she had I made a diagnosis of a chronic fibroid pulmonary tuberculosis and I said "Should be suspected." This is on the notes of eighteen years ago—should be suspected—and also having cavities and that was all I could do—suspect them—suspect that pulmonary area tissue was fractured because I had no way to prove it without an x-ray. The mental condition of this patient was, "This Dr. Brunson is a wonderful man, makes you feel good whether you do or not."

Q.—Describe the appearance of Mrs. Rachels. A.—I do not think I have that with me.

Q.—Did you examine any other patients? A.—A Mr. Martin.

Q.—Tell us about Mr. Martin. By the way, first, do you recall the circumstances under which you went out to see Mr. Martin? A.—No, I do not think I do.

Q.—Do you know whether or not Dr. Brunson drove you out to Mr. Martin's home? A.—That I am not sure of, as I look back over the years, he may have.

Q.—Go ahead and tell us about Mr. Martin. A.—Mr. Martin was 49 years of age when I examined him. He was sick for ten

years and in bed fourteen months. He was getting serum treatments but gave them up because he was running a temperature at that time of 103 to 104. He took about forty treatments by the Holderness-Brunson method and the temperature returned to normal and pulse normal and was up and about and gaining in weight, but the physical examination of his chest revealed an active case of pulmonary tuberculosis when I saw him. He had moist rales all over the right side and particularly in the base and in the left upper lobe but had no hemorrhages and gave no history of hemorrhages. Because of the duration of the time of his illness I made a diagnosis without x-ray and no sputum reported to me or clinical report of a chronic fibroid pulmonary tuberculosis in the far advanced stage.

Q.—What was your conclusion of that? A.—That that case was still active and far from cured.

Q.—Have you any other patients, Doctor, that you examined? A.—Not patients. I went to discuss the treatment at some of the sanatoriums.

Q.—All right, tell us about what sanatoriums you went to here? A.—I went to the Hendricks-Laws Sanitarium, where they had at that time a capacity of about ninety-five patients, situated on the northeast side of the city, and I interviewed the house physician, and he claimed that the medical society—

Mr. Quaid:—Your Honor, I believe the interviews with the house physician would be inadmissible. Any patients he himself saw, under the ruling of the Court, would have a right to have him testify about.

A.—I am not going to discuss any patients at the sanatorium.

The Court:—Just a moment. The Court sustains the exception; any statement that was made to him by some doctor, house physician, that portion the Court sustains exception to.

Q.—You can't tell anything, any conversation you had, Doctor. A.—Well, that is what it will be.

Q.—Tell us what you observed there, what you did? A.—I just discussed the treatment, and I would have to discuss what he told me, and the way he discussed it with me. Of course, it was an up to date, modern institution.

Q.—Did you examine any patients there? A.—No, because it did not concern the Holderness-Brunson treatment.

Q.—Did you go anywhere else? A.—Homan Sanitarium.

Q.—The Homan Sanitarium? A.—And that would be about the same thing.

Q.—And you did not examine any patients at the Homan Sanitarium? A.—No, I did not. I just discussed the treatment with them. I wanted to see what the local physicians thought of the treatment.

Q.—Now, what was your conclusion regarding these six patients that you examined, with reference to whether or not they were still afflicted with tuberculosis? A.—There were seven patients.

Q.—Seven patients? A.—Two I called on were not at home. And I visited two sanatoriums. My conclusions were these: that every case I saw, as I stated, ranged from 35 to 60 years of age, one younger, one at 30, but all sick for a long time, before they came to the Holderness-Brunson Clinic, all sick for years. As you have noticed, the diagnoses were chronic fibroid pulmonary tuberculosis, all in the far advanced stages and active. And in some of those, and only those that presented hemorrhages, did I make a diagnosis of chronic fibroid ulcerative pulmonary tuberculosis. The conclusion was this too: they were sick for many years. Chronic fibroid pulmonary tuberculosis is known to do that in our clinical experience; the patients do not die suddenly unless some accident, some pathologic accident, as an acute pneumonic process complicating the chronic condition, or we have a terminal meningitis, or a spontaneous pneumothorax where it kills suddenly. But without these pathologic accidents the patient lives on, lives on, lives on, and can live from the time of his childhood and to the age, and I have seen it so, of 90. And in all of that time the clinical course will be one of apparent healing, a quietude of his illness, or quiescence, and acute exacerbations that will appear as colds, ordinary colds or influenzal attacks, or pneumonic attacks, and often misconstrued by the physician and not diagnosed. So that with these improvements they were thought to be cures. They were not so! It was only that their symptoms subsided, and, as I said, the course is like the waves of the sea, up and down, over a period of years, one year, two years, ten years, yes, and forty years. And when that symptom complex is down, was that a cure? That symptom could be like normal for six, eight or ten months, and then again activity, and then again a wave. But when we examined the patients we found clinical activity of pulmonary tuberculosis and not a cure.

Q.—Who gave you this list of patients to be examined? A.—Somebody at the clinic; I don't know whether it was a clerk or Dr. Holderness or Dr. Brunson, but I got it.

Q.—For what purpose did you examine these patients, that is for what determination? A.—Could I extend on that a little bit?

Q.—Yes. A.—I came down here to find out about a cure of tuberculosis. With all of the publicity in the papers I was sent down here by my superior officer, who was very anxious to be first on the ground with a cure in Chicago. And he sent me to come down here to find out how it is used, and what it is, and whether they have cures, but I did not find anything.

Q.—Were these patients given to you as being cured patients? A.—I asked for their cured patients. I wanted to see how the treatment was given and asked them to give me only cured patients to examine.

Q.—Doctor, is there a cure for tuberculosis? A.—Yes, sir.

Q.—Will you tell us what it is? A.—Rest.

Q.—Anything else? A.—And rest.

Q.—Tell us what you mean by rest? A.—A General rest! When a case is active and acute, and running temperature, and is sick, or even without that if he has a lot of physical findings, and particularly subject to hemorrhages because of cavitation in his lung, then rest in bed. There is general rest of mind and body, but rest in bed, the temperature recedes, the pulse gets slower, and the lungs do not have to work so hard if you have your patient resting generally in bed. But the more modern treatment with rest has been by collapsing a diseased lung, or lungs. In other words, when you break a leg the doctor doesn't give you medicine for a broken leg. He rests it, and he rests it with a cast, a splint, a splint with casts or what not. When the lung is sick we put that lung in a cast, we splint it, but not with plaster of paris or steel or wood. We splint it with air. We splint it by paresis of the muscles, and we splint it by removing the ribs. But rest is a cure for tuberculosis, and a cure without drugs, just like the fractured leg.

Q.—That is termed collapse therapy? A.—Collapse therapy is the term for it in general. There are many procedures to splint a lung, but in general they are called collapse therapy.

Q.—After that lung has been collapsed is the lung active? A.—Yes, sir.

Q.—Or is it just resting? A.—If we splint it by air it will be just so active as we please it to be. We can put the splint of air around it and hold it down to about 90 per cent of its original activity, to 80 per cent, to 70 per cent, to 50 per cent, but never much more than that. In the modern treatment with air we do not crush the lung down to the mediastinum—that means central root of the chest—but we keep it on the hypotensive side and give our lung at least 40 to 50 per cent activity; but that is enough rest to afford a cure. If we do it by other methods of course we have not such voluntary control of the amount of rest.

Q.—Now, Doctor, how about a bacteriologic cure? A.—A bacteriologic cure is impossible. You can't get a bacteriologic cure. Once you have *Bacillus tuberculosis* in your body it will be there for the rest of your born days. It may be closed even in a tombstone—a tombstone of the healing of tuberculosis—and that tombstone is a calcified gland and is actually a stone; and yet that stone harbors within itself *Bacillus tuberculosis* so that the bacteriologic cure of pulmonary tuberculosis is not.

Q.—Doctor, does every person have tuberculosis bacilli? A.—No, sir.

Q.—Will you tell us, Doctor, how you classify the progress of tuberculosis, that is a patient under treatment? A.—Yes. We classify a patient under treatment. He comes to our institution; he has an active, a sick case of pulmonary tuberculosis. We put him to bed to rest, and he has temperature and has clinical symptoms that he complains of on the day of admission, but within a week or two they will disappear on bed rest. We will then classify him as an improving case. Then if his clinical symptoms are absent for two months and his sputum is positive or negative—it does not matter—but for two months he has been without clinical symptoms, without complaint; we call that a quiescent case. The next step up is the improved case. Now, a quiescent case. If those clinical symptoms and his sickness have been much improved, and practically negative for three months—but this time his sputum must be clean—we call him an apparently arrested case. If the same holds true for six months we call him an arrested case; and if he has been without symptoms or signs or x-ray findings, and the sputum negative for two years, we still do not call him cured; we call him apparently cured after two years. Now, that gradation of classification of the tuberculous individual under

the treatment is a classification of the National Tuberculosis Association.

Q.—Doctor, is it or is it not a fact that it is much easier to determine that a T. B. victim is not cured than it is to determine that the victim is cured? A.—It is a very difficult thing to determine whether a T. B. victim is cured; it is much easier to determine that he is not cured.

Q.—Why? A.—Because when the individual with T. B. that once has had a storm in his chest and in his whole physical anatomy, and to see that storm die down and then to determine when it is absolutely out, or there is still a smoldering fire in his body, is a mighty difficult thing; but to find he has activity, sick, with the fire going full blast, it is so much easier. In other words, it is easier to see a fire than to see a smoldering ash under a dampened heap.

Q.—Doctor, you are familiar with the treatment administered by Drs. Holderness and Brunson, is that right? A.—Yes, sir.

Q.—And you were familiar with the nature of that treatment? A.—Yes, sir.

Q.—Why is the Brunson-Holderness treatment dangerous?

The Court:—A little bit louder; the Court can hardly hear you.

Q.—I say, is the Brunson-Holderness method of treatment dangerous? A.—First, I came here and I received no formula of the medication, and without knowing a formula for a medication it cannot be recognized as a formula. For myself, Hruba is my name, and if I had not been recognized by my name I would not be here today. So without formula there is no recognition. Secondly, the treatment had not been established by the medical societies of the country, or even here in the local community, had not been recognized by the National Tuberculosis Association at that time, nor by the state medical society or tuberculosis association at that time. So unrecognized and not established. Now, dangerous, indirectly, to the patients in that he was wasting his time on an unrecognized and not established treatment, valuable time to have had with established and recognized treatment, valuable time to prevent a spread of his disease. Indirectly! Directly, dangerous in that the treatment consisted of inhalation, at the time I was here with an atomizer—but he was already contemplating forceful methods of putting in the oil. To handicap a diseased part of the body with anything foreign to cope with is adding stress and strain to those organs. Now, thirdly, ambulatory treatment of chronic fibroid and ulcerative cases of pulmonary tuberculosis—cases in the main in their far advanced stages—and I am sure more positive sputums than I could detect here—dangerous to the home and the community and the state and, yes, to the country, because tuberculosis is a communicable disease and these chronic fibroids are the spillers of that infection; and that is what makes tuberculosis go on and on and on; and in established treatment we recognize that these chronic fibroid cases must be isolated until their sputum is clean of the germ of consumption.

Q.—What do you mean by ambulatory treatment? A.—Ambulatory treatment is a treatment so that the patient is not confined in any institution but is allowed to be up and about and around.

Q.—Doctor, why did you call the Holderness-Brunson treatment a fake? A.—I don't know that that is a direct quotation, sir. I pointed out the dangers and made my reports, and I sent them in.

Q.—I think there was something said about your terming the treatment a dangerous fake. Explain that, please. A.—Yes. I termed it a danger, and of course that may be admitted to the definition of fake.

Q.—All right, now, explain why? A.—Because it is dangerous. It is not recognized, and it is not an established treatment.

Q.—Is that for the same reasons that you have just related here? A.—Yes, sir.

Q.—I think that is all.

ON CROSS EXAMINATION

Questions by Judge Sweeney:

Q.—Doctor, you came here in July 1921 was it? A.—July or August. I don't know just the date, but it was somewhere between June and September.

Q.—How long were you in El Paso on that visit, Doctor? A.—I think three or four days.

Q.—Three or four days? How many visits did you make to the clinic? A.—One, the first morning.

Q.—That was the first morning you were here? A.—Yes, sir.

Q.—You never returned after that? A.—I don't believe so.

Q.—Now, the names of the individuals, these six individuals that you gave, from whom did you receive those names, Doctor?
A.—At the clinic.

Q.—From whom, do you know who gave them to you? A.—I don't know whether it was a clerk or Dr. Brunson or Dr. Holderness.

Q.—Now, your memory at that time would be infinitely better than it would now, would it not, Doctor? Your memory and your statements at that time would be clearer? A.—At the time, yes.

Q.—Yes, than they would be at this time? A.—Yes, sir.

Q.—Now, in the statement in the paper that has been admitted by the Court you state: "First of all, I wish to thank Mr. Griffin and Mr. McLean for the assistance given me during my investigation. Through their courtesy I was afforded every opportunity to obtain the names and addresses of some of the patients who, it was claimed, had been cured by this treatment." Now, according to this statement you obtained the names from Mr. Griffin and Mr. McLean. Now, that is probably a fact, is it not, Doctor? A.—No. By introduction, you see. If it was not for Mr. McLean and Mr. Griffin I would never have been here, and it was by their introduction to the clinic that I was able to receive the names.

Q.—You did not receive the names from them? A.—I don't remember that I did. I certainly would have had to have the permission, and I did consult and meet with the doctors at their clinic before I did anything, and it was with their permission and consent.

Q.—Then you examined these patients at the clinic or at their homes? A.—Both places.

Q.—Both places? A.—Yes, sir. I did not take the names and addresses of those that I examined at the clinic because I wasn't so much interested in the patients or clinic either. I wanted to see cures; I wanted to see the cure and the method of cure.

Q.—You wanted to see those who had been cured there? A.—Yes, that was it.

Q.—You were not interested in the patients taking the cure? A.—Because I couldn't treat them; they were Drs. Brunson's and Holderness's patients. I didn't have any interest in their practice. I wanted to see cured patients, and how it was done.

Q.—You were not interested in the patients who were taking the cure at that time? A.—No.

Q.—Now, you say that most of the patients that you visited claimed their temperature and pulse were normal, sputum negative since they had begun the treatment at the clinic, is that correct? A.—By their own report, and in one or two instances by the report of the laboratory of the Brunson-Holderness Clinic.

Q.—Some stated that they had temperature and pulse, and explained this was perhaps due to the fact they had not taken the treatment long enough? A.—Yes.

Q.—Those are correct statements, are they? A.—Yes.

Q.—Now, you state that "Realizing that I would not be able to make much headway in my personal talks with the patients in their homes, through the kindness of Messrs. Griffin and McLean I was introduced to and permitted to talk with the patients at the clinic?" A.—Yes, they introduced me to the clinic, you see, and Dr. Holderness was there, and he showed me the technic.

Q.—Dr. Holderness or Dr. Brunson? A.—Dr. Holderness I believe it was.

Q.—You were here, you say, about five days at that time? A.—It is hard for me to recollect that.

Q.—I forgot your statement. A.—Three or four or five days, something like that; I don't know.

Q.—In the examination of the patients that you made you made them, those examinations, under the impression that those patients were cured patients? A.—Yes. I was looking for cured patients, yes, sir.

Q.—Did you examine or see the administration of the medicine to any of them, Doctor? A.—Yes, sir, at the clinic the first morning I was here in El Paso.

Q.—That was by an atomizer? A.—Yes, sir.

Q.—Your present form of administering to tuberculars, I believe you call it, the rest cure and fresh air? A.—Rest, sir, for tubercular individuals rest and fresh air.

Q.—Fresh air and rest? A.—But the most important thing is rest, general and local.

Q.—When was the fresh air and rest treatment first tried by the doctors? A.—In Germany; the first sanatoriums were originated in Germany.

Q.—That was by Dr. Brehmer? A.—Brehmer and Dettweiler.

Q.—Now, as a matter of fact in 1845 Dr. Bodington was the first man— A.—There is always a dispute in history, sir.

Q.—Then twenty years after Brehmer Dr. Bodington was driven out of the practice of medicine by the medical fraternity by reason of his theory of the fresh air and rest theory? A.—Yes, sir.

Q.—Then Dr. Brehmer started it in Germany twenty years afterward and it then became general through Trudeau? A.—1884.

Q.—In 1870? A.—1884, at Saranac Lake.

Q.—In the Adirondacks? A.—In the Adirondacks.

Q.—Now, since that time the medical fraternity has administered treatment for tubercular patients by giving them the rest cure and the fresh air cure, that is a fact? A.—Yes, sir.

Q.—They have no specific for tuberculosis? A.—No, sir.

Q.—Now, Doctor— A.—No specific medication.

Q.—Medicine is an inexact science, is it not; it is not an exact science? A.—There is no such a thing, sir, as an inexact science. Inexactness means that medicine had been the practice of the art of medicine, but as the centuries roll out becomes a more exact art.

Q.—As a matter of fact it is now inexact by reason of the fact it is constantly changing, it is not an exact science, isn't that a fact? A.—No, because we still have lots to find out about it. A science is an exact thing, and it is always that way.

Q.—Science is always exact? A.—Yes, sir.

Q.—So medicine is not necessarily a science? A.—Not yet, sir, but it is a more exact art than it was a few decades ago.

Q.—It is moving along to still higher heights by reason of experimentation? A.—Yes, sir.

Q.—Now, when you treat your patients, or when a patient comes to you, you stated on direct examination that that patient was put to bed, and what is done then, Doctor, when you put the patient to bed for rest? A.—All right. A patient comes in to the sanatorium, and of course we put him to bed, and then that patient gets the most grilling examination that this more exact art of the practice of medicine can give today, his urine, his stool, his stomach, his blood, his everything, is gone over and he is studied in what we call the admission department, and then—

Q.—Excuse me just a moment now. How long does it take to do that, Doctor, to give him that thorough examination? A.—It all depends on the case. Some patients will graduate, as we will say, from the admission department to the institution proper, but when he goes into the institution proper he has his ticket for treatment.

Q.—Just a moment. When he goes in first. A.—Yes.

Q.—How long does it take to get his ticket, as an ordinary case? A.—As I say, it depends on the case. Just as quickly as he is diagnosed thoroughly with all of his complications and associated conditions about him, then he goes to conference. He does not go as a patient.

Q.—Just a moment. You have not yet answered my question, Doctor. How long does it take to give him this physical examination that you speak of? A.—Let's say the average of a week.

Q.—Then he gets what you call his ticket? A.—Yes.

Q.—Then he goes to what department? A.—After a conference—this ticket is not given until the history of the case is surveyed, not by one physician, or a group, we call that clinical conference, and the treatment is determined on. Then he is turned over to a certain department of that sanatorium or that institution for the treatment that had been advised by the conference.

Q.—That consultation just takes a day or two or three days, or a short time, I presume, does it not? A.—It is about a week on the average, but the conference only takes a morning.

Q.—Then he goes into what? A.—Into the institution.

Q.—Into the institution? A.—Yes, sir.

Q.—And into bed? A.—Yes, sir.

Q.—Under a certain treatment? A.—Yes, sir.

Q.—Then how long do you keep them in bed, Doctor? A.—That is very, very variable.

Q.—Yes, I know that is. A.—We keep them until the symptoms of toxemia and symptoms of destruction of tissue, and symptoms of the reflex action of the poison that affects the mind and nervous system are all subdued.

Q.—That on the average patient takes how long? A.—That cannot be given.

Q.—Approximately? A.—There are so many different types of tuberculosis I can't give that.

Q.—With all your vast experience taught you with reference to the length of time it takes to eliminate all of these destructive poisons from the system and reduce their temperature, and build up their system so that they can stand and so that nature will commence to assert itself? A.—Every individual is an individual, and there is no comparison of the human individual, and there is no more protean disease than pulmonary tuberculosis, or tuberculosis anywhere in the body. So that that cannot be answered.

Q.—It cannot be answered? A.—No, sir.

Q.—It will vary perhaps from a month—do you turn them out within a month? A.—No.

Q.—Two months? A.—Sometimes.

Q.—Frequently? A.—We usually like to keep them there—we have a basis for that, because the disease is so protean, because individuals are so different, humanity is so different, every human being is different, one from another, we like to strike an average. So we like to have them in the institution a minimum of three months, but better would it be to have a minimum of six months to even a year. But because of the overcrowding of institutions and sanatoriums in the metropolises of our country we have to get beds for the poor sick and get them on their feet just as soon as we can; but we do not let them go; we still keep them under observation in our extramural clinics.

Q.—You keep some patients for as much as a year? A.—No, when they are in the extramural clinics they are there for the rest of their lives; unless they move from the city limits, they are under observation always.

Q.—They are there permanently then? A.—They are there permanently unless discharged apparently cured.

Q.—Now, your purpose and your idea and your intentions are to keep them about three months so as to determine whether or not? A.—A minimum of three months.

Q.—A minimum of three months? A.—Three months' observation, and if they are negative and their symptoms are gone then they go to the extramural clinic for watching.

Q.—By reason of that system, you are doing that for the purpose of ascertaining whether or not they are amenable to the treatment, and whether they are improving? A.—Yes, sir.

Q.—And then after they are there six months it is your determination, more or less, that may be final, and you then try to move them on and get them out? A.—Yes. And the greatest determining factor is the sputum positive or negative. When I say positive or negative I mean, by exhaustive tests of that sputum, and by culture and by concentration.

Q.—That is the only way, as a matter of fact, that the medical profession can determine whether they are responding? A.—There is no greater sign for the measurement of pathologic activity or the smoldering fire in the body than that little bug in the sputum.

Q.—I stated that is the system that the medical fraternity follows for the purpose? A.—Yes, sir, that is the National Tuberculosis Association—

Q.—For the purpose of ascertaining whether or not they are amenable? A.—Yes, sir.

Q.—Now, it is a fact, is it not, Doctor, that in the collapsing of a lung, when you collapse a lung and you throw these splinters and boards around them that you are speaking of, they still continue to breathe, don't they? A.—I didn't speak of any splinters or boards around the lungs, sir.

Q.—I misunderstood you. A.—I didn't speak of any splinters or boards around the lungs. I said an air cushion, air cast, I spoke of it as a splint and boards around a broken leg, broken bone.

Q.—You spoke of it as a splinter of air, of air around the lung? A.—A splint of air.

Q.—They continue to breathe, do they not, when that splint is there? A.—Oh, yes.

Q.—So the lung is not inactive, is it? A.—Not wholly so, sir.

Q.—Then when you collapse a lung, when you have a lung collapsed by taking out a rib, for illustration, why is that done, Doctor? A.—To collapse the lung, sir.

Q.—When you put a splint of air in there do you take out a rib? A.—No, sir, but we do what we call extrapleural pneumothorax. Now, you see, most extrapleural pneumothoraces are done by the intrapleural method, meaning in the normal physiological space between the lung and the thoracic cage, that is the common form of pneumothorax—that is where we put the air splint in and splint the lung down as you do a broken leg. You

asked do we remove ribs. Not for that type of pneumothorax, but there is another type called extrapleural pneumothorax. There we must remove a portion, usually the third or fourth rib, and that usually is done in the posterior of the chest. Then the surgeon strips the lung down, and after he strips it down then removes only the one rib, then he injects his normal salines and injects air later as the case goes on.

Q.—That is usually done for the purpose of getting the pus out, is it not? A.—That is done, sir, to hold the lung quietly for it to heal, not to throw the pus out, but to hold it still.

Q.—The pus remains right in the lung? A.—No.

Q.—If there is any? A.—No. It heals, is spit up and cleans it up. About pus, let's not talk pus. Let's talk germ of consumption. This result of collapse therapy, that 60 per cent of the cases that are put on collapse therapy are cleansed, the sputum is cleansed of the bacillus tubercle. In other words turns from positive to negative.

Q.—That is practically washing the lung off? A.—It is what?

Q.—You say it is cleansed? A.—The sputum is cleansed of the germ, not the lung.

Q.—Now, Doctor, you stated that operation is down now to about 60 per cent, I believe you said, did you not? A.—The sputum is cleansed in about 60 per cent of the cases that are treated by the general term collapse therapy. I did not mention any specific form of collapse therapy, but any type of collapse therapy where the patient is advanced enough to have pathology in his chest and allow him to have collapse therapy 60 per cent of those cases are cleansed, their sputum is cleansed of the germ of consumption.

Q.—What percentage of the collapsed lung is available for breathing? A.—That depends.

Q.—Approximately? A.—As I explained before, with the air cushions we can control the various percentages of functional activity of the lung. That is determined by the amount of pathology present before the treatment started.

Q.—Has that been of recent origin, Doctor? A.—Carson Smith of 1829 discovered collapse therapy, and even before that, even in the wars of Rome, the doctors of Rome where the soldiers were punctured by bayonets and the lungs collapsed and had abscess and pus and found they were healed, they thought in those days there was something in collapse therapy. But the one who brought it out in 1829 was Carson Smith.

Q.—In those days you collapsed more lungs than you do now? A.—No, no, no, here, I will give you a direct answer to that. I was medical superintendent in the Municipal Tuberculosis Sanitarium in 1918. I worked there until 1923. You ask me "What percentage did you have, Doctor, in that institution?" That is on collapse therapy and I will tell you about 3. Another administration after mine, what percentage did they have in that institution? About 10 per cent of the cases on collapse therapy.

Q.—It is increasing? A.—Today I will tell you that 60 per cent of our institution, which is 1,250 patients, are on collapse therapy and 60 per cent of those there before they leave have clean sputum.

Q.—How long do they stay in the institution before they leave? A.—As soon as the sputum is negative and clean they are sent to the extramural for observation for the rest of their born days as long as they are in the city limits or classified by the attending physician in extramural cases as apparently cured cases.

Q.—Now, Doctor, is it possible for an individual, for a human, to have tubercle bacilli in his system and it not be active? A.—Yes, yes, yes, I think I have them in my system.

Q.—I think you do, too. A.—I have worked with them for twenty-five years, so I know I must have them.

Q.—Having them there you have a nice case of tuberculosis? A.—I have no tuberculosis, I am just an infected individual as most of us are.

Q.—You are not dangerous to us are you, Doctor? A.—No, sir.

Q.—In speaking of the formula, the Holderness formula that you came down to investigate—A.—Yes, sir.

Q.—You stated that your report was based on the fact that there was no recognition of that formula and that it was not recognized by the Tuberculosis Association and not established. That is a fact is it? A.—Yes, sir, we couldn't get the formula. I asked about the formula. I couldn't get it. I didn't try very hard.

Witness excused.

SATURDAY, JULY 8, 1937

PRIMARY TUBERCULOSIS IN ADULTS

Recently Soper and Amberson¹ called attention to a striking change in the concept of pulmonary tuberculosis in adults. The older German phthisiologists and pathologists, basing their belief largely on necropsy evidence, declared that every man at the end of his life has some tuberculosis in the apex of his lung. The researches of Behring gave much support to the prevailing idea that almost all human beings were infected with tubercle bacilli in infancy or early childhood, that this primary infection in the great majority of cases became localized, encapsulated, inactivated or cured, and that a reinfection or a superinfection took place in a certain number of people under the influence of endogenous or exogenous factors. The introduction and employment of tuberculin testing by the Pirquet method further confirmed the belief in early universal infection with tubercle bacilli. In fact, the test came to be considered clinically unimportant above the age of 12, for everybody then was considered to be tuberculin positive.

As the result of the campaign against tuberculosis in man and in animals a generation of children and young adults developed who did not exhibit allergic sensitivity to tuberculin, who in other words escaped primary infection. Heimbeck of Oslo found that 52 per cent of the students entering a school of nursing reacted negatively to the tuberculin test. In the last fifteen years tuberculin testing of large groups of young adults in the United States has been carried out. According to the seventh annual report of the Tuberculosis Committee of the American Student Health Association for the academic year 1936-1937, positive reactors among 32,281 students amounted to only 30.5 per cent. Thus the infant of today has a much better chance of growing to adult life without contamination with tubercle bacilli than infants of former generations. This new generation, a goodly portion of which has never been infected with tubercle

bacilli, presents a new problem, namely that of primary infection in adults. Are such persons more liable to tuberculous infection when exposed and will the ensuing infection be more severe than in those who had been infected in infancy but were not ill? Heimbeck² believes that primary infection conveys a certain amount of protection and that tuberculosis allergy is tuberculosis immunity. He vaccinated the negatively reacting nurses with BCG and in a study extending from 1924 to 1935 showed that the group of 287 nurses who were vaccinated till allergy (Pirquet's reaction) was produced gave a morbidity of 8.3 per cent per thousand observation years, a morbidity slightly lower than that of persons who have passed the primary infection without disease. The highest morbidity was in the nurses who were positive at the time of admission.

Differentiation between the primary form and the superinfection forms of the tuberculous disease is difficult. According to Soper and Amberson the primary form can be suspected when the individual has been so closely followed with the tuberculin test that only a short period has elapsed after a change to a positive reaction and the roentgenogram shows a lesion in the lungs previously not present and found on observation not to be due to some nontuberculous infection. They state further that many studies indicate that more tuberculosis develops on exposure among the tuberculin negative than among the tuberculin positive. Primary infection in adults, other things being equal, appears to be distinctly less grave than in infants and no more grave than in older children. The great majority infected in young adulthood show few symptoms and apparently few serious effects. However, the number in whom the effects are serious is apparently far from negligible. To what extent these later primary infections influenced the high morbidity and mortality rate among young adults has not been definitely determined. Myers³ regards any lesion demonstrable by x-ray examination that appears soon after the tissues are sensitized as representing the first infection type of the disease. If a year or more has elapsed between the making of the tuberculin tests there has been ample time between the last negative and first positive reaction for the first type of infection to develop and also for reinfection to make its appearance. Since 1927 Myers has seen many students of nursing and medicine become contaminated with tubercle bacilli for the first time, the evidence of this contamination being a positive tuberculin reaction which appeared after the student was exposed to tuberculous patients. In a student body of 12,000 the number of those enrolled in the schools of nursing and medicine was relatively small, yet it gave an overwhelming preponderance of tuberculous lesions, indicating that the problem of tuberculosis among young adults is most acute among those students who while

in the line of duty come in contact with tuberculous patients. On the basis of observation of eighty-five cases of primary infection in adults, he concludes that young adults who have not been previously infected with tubercle bacilli become contaminated in large numbers during the course of training in some schools of nursing and medicine. In a small percentage of these the focus of disease when located in the pulmonary parenchyma attains sufficient size to cast a shadow on the x-ray film which can be visualized by the naked eye. The first infection type of tuberculosis, as observed in this group of adults, has resulted in no significant symptoms or abnormal physical signs throughout the entire course of development. Indeed, he states, the lesions in the majority of their cases would not have been known to exist had it not been for periodic tuberculin testing and the making of roentgenograms of the positive reactors. It apparently makes no difference at what time of life the first infection with tubercle bacilli occurs with reference to the average type of tuberculosis in human beings. Among those persons in whom, through exposure with patients with communicable tuberculosis, the first infection type of disease develops, whether in infancy, childhood or adult life, including the third decade, a considerable number will subsequently show a clinical form of tuberculous reinfection. Soper and Amberson likewise feel that the question of the existence of allergy to tuberculosis is less important than the question of exposure to infection. They urge a more widespread emphasis on prevention of infection and on early diagnosis, particularly by tuberculin and x-rays.

PRODUCTION OF ANTIBACTERIAL IMMUNITY WITH ARTIFICIAL ANTIGENS

A recent report by Goebel¹ on the production of artificial antigens which on injection into rabbits engender antibodies for type III pneumococci is significant in the development of immunochemistry. The most remarkable feature of immune reactions is their specificity. In attempting to elucidate the serologic specificity of proteins, Obermayer and Pick² investigated the changes in the immunologic reactions which occur when proteins are modified by denaturation or by the action of chemicals such as oxidizing agents, iodine or nitric acid. The possibilities of this approach were soon exhausted. For about a decade further progress was not made. Then a new method of attack was introduced by Landsteiner.³ This investigator demonstrated that

it was possible to synthesize an unlimited variety of antigens by chemically combining organic compounds with proteins, preferably by means of azo linkages, leading to the formation of so-called azoproteins. The new serologic specificity of such antigens was shown to depend on the substances (haptens) united to the proteins. The immune serums, however, reacted directly with the haptens, as shown by Landsteiner with his inhibition technic. Thus, while serologic reactivity was previously believed to be a property only of proteins, it was unexpectedly established that antibodies can react with a large variety of simple chemical compounds bearing no relation at all to proteins or to their component parts. Thus a new chapter in immunology was opened, namely the investigation of serologic reactions in terms of chemical constitution.

Now it was found that many natural antigenic materials, for instance bacteria, contain nonprotein substances (haptens) which give specific serologic reactions.⁴ In particular, it was discovered by Heidelberger and Avery⁵ that polysaccharides determine the specificity of many sorts of bacteria. Chemical investigation of these polysaccharides in pneumococci showed that each type is characterized by a special polysaccharide. For instance, the polysaccharide of type III pneumococci is made of units of an aldobionic acid, cellobiuronic acid, in glycosidic union.

Armed with these facts, Goebel prepared conjugated antigens (using the "azoprotein method") containing glycuronic acid, which, combined with dextrose, makes up the molecule of cellobiuronic acid. Remarkably, these antigens reacted in high dilution in antipneumococcus horse serums. In order to approximate more closely the chemical structure of the bacterial polysaccharide, an antigen was prepared from cellobiuronic acid. Antiserums were produced with this azoprotein. Then Goebel found that these immune serums agglutinated specifically type III pneumococci and gave capsule swelling with these bacteria. The climax of these experiments was reached when it was demonstrated that the serums gave passive protection to mice against pneumococci of types II, III and VIII, and the antigen immunized rabbits actively against infection with virulent type III pneumococci, establishing for the first time the possibility of immunizing against a specific infection with an artificially produced antigen.

These results are of interest regardless of whether or not they will find practical application. Their clinical use will depend in part on the relative merits of chemotherapeutic measures and specific serotherapy, now under clinical review in the treatment of pneumonia. How difficult it is to foresee what turns the therapy of bacterial disease may take can be seen from a startling recent communication by Dubos,⁶ who obtained

a substance from soil bacteria which, it is claimed, destroys all gram-positive cocci and in animal experiments has high protective and curative activity against different types of pneumococci as well as hemolytic streptococci.

INFECTIOUS POLYARTHRITIS IN RATS

The discovery of a spontaneous infectious polyarthritis in the wild and domestic rats of Java offers investigative opportunities heretofore unavailable and has already resulted in a major contribution to experimental medical technic. Two years ago Collier and Esseveld¹ of the Eijkman Institute, Batavia, observed an adult rat (*Rattus norvegicus*) caught in the suburbs of Batavia which exhibited a peculiar disease characterized by considerable swelling of both hind legs, unaccompanied by signs of disease in the internal organs. The Java pathologists were able to transfer this disease to normal rats by the plantar injection of arthritic joint exudate. About two weeks after such injection the bones of the injected hind leg became remarkably enlarged, x-ray examination showing not only increases in size but distortions in outline and exostoses. Two weeks later similar arthritic changes were usually demonstrable in the opposite hind leg and somewhat later in both forelegs. An occasional arthritic exostosis developed on one or more of the vertebrae of the tail. The infected joint cavities usually contained a cellular exudate, which was almost invariably sterile on routine bacteriologic test. Filtrates from such exudates were invariably noninfectious. The inner organs of the arthritic rats were apparently normal except for a slightly increased amount of fluid in the pleural and pericardial cavities. Afterward it was found that a fulminating type of polyarthritis could be produced in normal rats by injecting relatively large doses of arthritic exudates intraperitoneally or intrapleurally. Following such massive injections the arthritic changes appeared simultaneously in all four legs, often as early as the tenth day after the injection. Spontaneous recovery from the experimental infection was occasionally noted.

More recently Collier² has reported that the disease could be transmitted to white rats by scarification and by subcutaneous and intraperitoneal injection as well as by the plantar route. Similar experiences were obtained with field rats. In spite of many careful attempts, it has not yet been possible to cultivate a micro-organism that might be considered to have etiologic significance. Transfer experiments using other than joint tissues obtained from sick rats indicate that the causative agent is not confined to the joints. Collier also reported immunologic studies using fifteen white and seven field rats which had recovered from the

disease. Of the fifteen white rats reinoculated only one contracted the disease; in all seven white rats the reaction remained negative.

Thus it appears that once rats have overcome the polyarthritis they exhibit a strong resistance to reinfection. As yet no instances have been found in which complement fixing, precipitating or neutralizing antibodies have been discovered in the serum of immune rats. This disease presents exceptional features of parallelism with chronic rheumatoid arthritis in man and offers promise of yielding information of practical import.

Current Comment

AS OTHERS SEE US

In the concluding chapter of a "diary" entitled "American Journey" by Mr. W. H. Ogilvie,¹ surgeon of Guy's Hospital, London, several comments on the American scene deserve attention. The factors that favor good surgical work in America are self evident, Ogilvie says (and include courageousness, independence, self sufficiency, distrust of tradition, pioneering and ability to make quick decisions); but he also notes two adverse factors. One of these is the remarkable lack of individuality in instruments. The tendency of this country is to mass production, and mass production gives everybody goods of admirable finish and appearance and of remarkable quality for the price, but it militates against personal adaptation and fine workmanship. The second adverse factor Ogilvie hesitantly refers to as the "Halsted tradition." The followers of this tradition in the United States "are carrying out the technic of 1910 with all the reverence and attention to detail of a religious exercise and seem to have lost sight of the object with which these details were once introduced." The usual method of dissection of the axilla with a knife is distressing to watch, Ogilvie states; the surgeon takes more than an hour to do part of the operation for which he should take ten minutes, and, more important, the vessels and planes are not nearly as clean; there is more bleeding and more trauma than by the use of a blunt instrument. Graduate surgical teaching in America is, he feels, better than that in England but the undergraduate teaching inferior. American undergraduates appear to be taught didactically, and their training in responsibility comes later and possibly too late. Many textbooks that are published consist of a thin skeleton of facts clothed in a large body of verbiage and pseudoscience. The most penetrating summary of American surgery, Ogilvie feels, is quoted from another Englishman: "American surgery is like American football; they run about like hell for ten minutes and then stop and have a conference." The record of Mr. Ogilvie's peregrinations spreads through many issues of *Guy's Hospital Gazette*, and his views are interesting even if, occasionally, they seem to be based on what might be called cursory data and insufficient observation.

ORGANIZATION SECTION

AMERICAN MEDICAL ASSOCIATION STUDY OF MEDICAL CARE

REPORT OF COMMITTEE ON MEDICAL ECONOMICS OF THE CHICAGO MEDICAL SOCIETY

1. *The Committee's most important and final conclusion is that the supply of medical care in Cook County is sufficient to meet the active demand for all urgent requirements. This statement is substantiated by the following:*

(a) A spot survey by the Nursing Division of the Chicago Board of Health's visiting nurses during the months of September and November 1938 and January 1939 reached 14,808 persons, of whom only thirteen had some difficulty in obtaining medical care.

(b) Our direct study of the experiences of 617 families averaging 3.5 persons each and having an average stated annual income of \$680.17 for each family for which figures were obtained (567 families for 1937 and 575 for 1938) showed that more than 93 per cent had stated specifically that they had never failed over a period of several years to obtain any form of medical care which they had tried to secure.

Some conception of the enormous amount of services now being supplied as part of the free and part-pay medical care which makes this conclusion possible is given by the following summary:

(a) One thousand two hundred and forty physicians and 145 dentists reported that in 1937 they referred 38,816 persons and 1,731 persons respectively for *free medical and hospital care* or *for free dental or medical care*. If the entire memberships of both professions had referred one half as many persons proportionately as did this sample group of 18 per cent and 3 per cent of their total memberships in Cook County, the estimated total number of persons referred for free medical or hospital care would be 107,822; and for free dental or medical care the estimated total number would be 28,850.

(b) Nine hundred and fifty-five physicians and 207 dentists reported that in 1937 they accepted for free care or for pre-determined reduced fees 173,188 persons and 4,406 persons respectively who had been referred to them from various agencies. One fourth of the proportionate figures for the entire professions would be 309,264 persons and 9,072 persons respectively. It is possible that the number of referred patients came largely from the Chicago Relief Administration and, as only approximately 38 per cent of the physicians and dentists are on the panel for assignment of relief patients, it seemed best in making this estimate to cut the proportionate figures of referred patients for the entire profession to one fourth instead of one half.

(c) Twelve hundred and eighty-nine physicians and 271 dentists gave free service in 1937 to 95,884 persons and 6,935 persons respectively who consulted them directly and voluntarily. Half the proportionate figures for the entire professions would be 251,005 and 55,480 persons respectively.

(d) Two hundred and seventy-eight physicians reported that in 1937 they had done free 24,978 preventive medical services such as Schick tests, toxoid injections for immunization to diphtheria, smallpox vaccinations and Mantoux (tuberculin) tests. Half the proportionate figures for the entire profession would be 303,131 free services.

(e) Four hundred and fifty physicians reported that in 1937 they had given free service to 5,299 obstetric patients. One fourth of the proportionate figures for the entire profession would be 19,842 free obstetric patients. Six hundred and twenty

of the 1,518 physicians, or 40 per cent, answered "none" with regard to the number of obstetric patients cared for in 1937 because they did not practice obstetrics; therefore it seemed best in making this estimate to cut the proportionate figures of free obstetric patients for the entire profession to one fourth instead of one half.

(f) Two thousand two hundred and seventeen physicians kept count day by day of the number of patients treated in their entire practice for periods of one week; part of these periods were in July 1938, part in October and part in January 1939. During these periods the entire practice of these physicians amounted to 129,430 patients, of whom 23,588 were served without charge and 2,096 were referred to some other source for free care, making a total of 25,684 persons treated free and/or referred elsewhere for free service. The proportionate figures for the entire profession would be 235,127 free patients. Six hundred and thirteen of the 2,217 physicians reported doing 2,342 free operations in the three weeks. Similarly, 423 dentists reporting treated in all 20,196 patients, of whom 1,488 were treated without charge and 169 were referred elsewhere for free care, a total of 1,657 patients. The proportionate figures for the entire dental profession would be 48,026 free patients.

(g) There were provided 2,751,465 free hospital days of care in 1937 in addition to 129,916 free days of care in related institutions such as the Chicago Home for Incurables, the Cradle, Salvation Army Booth Memorial, Grove House for Convalescents and the House of Correction Hospital.

(h) Outpatient clinics in 1937 gave service free or for minimum charges to the amount of 2,851,223 outpatient clinic visits.

(i) The County Physicians' Service made an estimated total of 79,656 free home visits in the city of Chicago for the year ended Nov. 30, 1938.

(j) The Chicago Relief Administration furnished medical care in 1937 to approximately 25,000 persons a month. In the course of five years it paid approximately seven million dollars to hospitals, dispensaries, physicians, dentists, pharmacists and for home nursing and other medical services to relief clients on a reduced fee for service basis. Such services included antepartum and postpartum care with some home deliveries, including nursing service from the Chicago Maternity Center. The effective participation of the Chicago Medical Society's Advisory Committee on the Medical Care of the Indigent and Recipients of Unemployment Relief has been one of the outstanding contributions to this work.

(k) Medical care to a total of 9,210 persons was furnished by seventeen of the public relief agencies in Cook County outside of Chicago.

(l) Eight organizations provide visiting or public health nursing services in the homes of the low-income patients, usually free or occasionally at a nominal cost averaging 25 cents per visit or included in the premiums paid for industrial insurance policies. In 1937 these organizations made 1,657,555 visits to 830,532 patients in Cook County.

(m) Incomplete figures from 149 private welfare and relief agencies show that 24,052 persons were furnished medical care. Sixty-four pastors arranged for medical, dental or hospital care for 721 persons. If the entire group of 1,266 pastors consulted did half as much proportionately, they found ways of obtaining such services for 7,131 persons.

(n) The medical inspection provided by schools amounted in 1937, in Chicago alone, to 201,941 visits by 145 physicians and 147 nurses, not including eighteen supervisors, to public and parochial schools and 34,089 visits to the dental clinics of the Dental Hygiene Unit of the Chicago Board of Health by children from the first to the fourth grades inclusive. For the county school districts outside of Chicago, equally complete statistical data are lacking, but if half as much service in proportion to the enrolment was provided for the pupils of elementary

With the exception of the omission of references to other pages of the report and the introduction in two paragraphs of sentences from a later section of the report in order to clarify statements, the material here published is taken directly from the summary prepared by the committee.

schools as is given in Chicago the foregoing figures for the city of Chicago would need to be increased about 11 per cent to cover all of Cook County.

(o) Two hundred and three pharmacies reported that in 1937 they compounded 24,229 free prescriptions, and 182 pharmacies compounded 55,716 prescriptions at cost or for reduced charges. Half the proportionate number of free prescriptions for all 1,996 pharmacies in Cook County would be 116,653 and half the proportionate number of reduced charge prescriptions would be 305,520.

2. *Notwithstanding the foregoing conclusion that the supply of medical care is sufficient to meet the active demand for all urgent requirements, the committee is convinced also that many very important needs exist.* Such needs include more facilities and better use and distribution of the present facilities especially for the purpose of recognizing and meeting the "actual needs" of the situation as . . . distinguished from the "active demand."

Our ideal must be to provide complete medical care, including both active demands and actual needs, for all who should have it. To achieve such an ideal means the formulation of measures which will provide medical care for the entire population at some periods in their lives, including those who seek it actively in addition to those who do not realize, and those who are unable to recognize, their own needs for it, and those who will not accept it. The accomplishment of such a program requires continuous and progressive improvement with respect to professional technics and mental attitudes of all who participate in giving any part of complete medical care. To this end, as the plan develops, the public at large must realize and evaluate the nature of this effort, its difficulties and successes. Thus there is emphasized the importance to all of public relations on a broad and sincere basis and of general education.

3. *The basic need of all, whether recipients or providers of medical care, is education.* The greatest need shown by the study is expressed by one word, "Education." It has been reliably stated that 10 per cent of the population does not wish medical care. Education includes not only that of the medical profession itself but of all the professions and technical groups having to do with improved and expanded health activities, as well as the education of the general public. The Committee's conclusions and recommendations which involve education include the following:

1. Education of the professions giving medical care as specifically recommended in connection with the necessity for the maintenance of the highest professional standards throughout the expanded medical care services which are already being developed over the entire country. Their development has perhaps been too much accelerated by the National Health Program of the Interdepartmental Committee on Health and Welfare Activities of the government. Too much speed in development may result in unsound plans, the failure of which can only result in an inferior quality of medical service.

2. The continuous participation of a committee of active and interested physicians in school health activities in cooperation with the school personnel, parent-teacher associations, the public at large and health departments, including the proposed single county health administration.

3. The education of the medical profession itself in cooperation with the pharmaceutical profession, whereby the splendid work of the Council on Pharmacy and Chemistry of the American Medical Association will become effective in the everyday practice of these professions in the reduction of the expense to patients of medication from the unwarranted prescription of proprietary preparations.

4. The education of the public particularly, and of all practitioners of medicine and dentistry, including those sections of these professions limited to the practice of specialties, so that

they all may know they have in the proposed nationwide Committee on Education in Regard to Medical Care a common source, through interpretation of research, of authoritative basic information concerning scientific developments and alleged developments in science.

5. Stimulation of college and university faculties to include health education in their curriculums.

4. *The dental profession of Chicago and Cook County has made a great contribution in dental service and toward education of its members and the public.* This statement refers particularly to the huge dental examination plan in the public schools of Chicago as described in detail in the *Bulletin* of the Chicago Dental Society of March 31, 1939, by the chairman of the society's educational committee. Through cooperation of the Board of Education, the Board of Health and the Mouth Hygiene Council, it is planned that by the close of the present school year 35,000 pupils in twelve very carefully selected schools and their parents will have been given this number of specific demonstrations of dental health standards and deficiencies as applied to individuals, with follow-up work in seven schools by parent-teacher associations having a dental health chairman for each school and committee members for each classroom, by the Mouth Hygiene Council in one school, by the teachers alone in two schools to be used as controls, and by Chicago Women's Aid Mothers' Clubs in two schools. The purpose of the follow-up is to influence the parents to have the dental corrections made. This latest accomplishment of the dental profession confirms the Committee in the belief that an improved program for dental care will be carried out as rapidly as circumstances may permit. The publication in December by the Chicago Dental Society of "The Cost of Dental Care under Health Insurance" by Peter T. Swanish, Ph.D., is another recent evidence of the effective consideration of the place of dentistry in a comprehensive program of medical care.

5. *The comments of those who returned questionnaires quoted in this report are of great educational value.* Much space is taken in this report by direct and indirect quotations of the comments of many individuals. Every questionnaire and accompanying letter used in the study asked for comments, promising specifically that the identity of the writers would not be disclosed, and the chairman of the Advisory Committee on Supply of Medical Care of the American Medical Association, at its San Francisco meeting and at least twice in Chicago during the last seven months, emphasized to physicians their importance above everything else. Careful reading and consideration of these comments will help us to see our problems of medical care as they are seen by others and will contribute to our understanding of the situation—this being part of the self education by the medical, dental, nursing, teaching and pharmaceutical professions.

6. *The report of the House of Delegates of the American Medical Association concerning the National Health Program is unqualifiedly endorsed and the limitation recommended in the proposed expansion of maternal and child health services is emphasized.* The Committee believes that the application of subitem 3 of section 3 of the House of Delegates' report to the proposed expansion of maternal and child health services (recommendation 1-B, title V) is of great importance. The section referred to in the National Health Program to which subitem 3 is to be applied reads as follows: ". . . to make available to mothers and children of all income groups . . . the minimum medical

services essential for the reduction of our needlessly high maternal mortality rates and death rates among newborn infants, and for the prevention in childhood of diseases and conditions leading to serious disabilities in later years." The qualifying subitem 3 which the House of Delegates would apply to this report reads as follows: "Any expenditures made for the expansion of public health and maternal and child health services *should not include the treatment of disease except so far as this cannot be successfully accomplished through the private practitioner.*"

7. *Compulsory health insurance in any form is inadvisable.* This is the belief of the Committee, which regrets that the National Health Program as transmitted to Congress was not accompanied by the report of the House of Delegates of the American Medical Association and that it did not include a definite recommendation for a Department of Health with a Secretary of Health as a member of the President's cabinet.

8. *The Committee recommends that the council of the Chicago Medical Society request the council of the Illinois State Medical Society to appoint a committee to draft a nonprofit group insurance plan of payment of physicians, with or without hospitalization benefits, to be presented to the Illinois State Medical Society's house of delegates at its next regular or special meeting for its consideration, the said proposed plan to be in accordance with the report of the House of Delegates of the American Medical Association in September 1938.* Many such plans are now reported in use in the United States and at the present time their legal authorization is before the legislatures of Michigan, New York, Ohio, Pennsylvania, Wisconsin and possibly other states. The following is a partial alphabetical list of the cities and states where such plans are now sponsored by the local medical professions:

Atlanta	Gary (Indiana)	Oregon (state)
Boston	Hawaii	Richmond
California (state)	Michigan (state)	San Antonio
Cincinnati	Milwaukee	Tulsa (Oklahoma)
Cleveland	Missouri (state)	Utah (state)
Columbus	New Orleans	Washington, D. C.
Dallas	New York (state)	Washington (state)
Denver	Ontario (province)	Wisconsin

The American Medical Association has stated that there are in the United States "more than 300 mutual benefit associations which collect dues from members and pay specified amounts of money for each day that the member is ill in order to assist him in the payment of his medical bills." Two such organizations are the Carnegie Illinois Steel Corporation's Employees' Relief Association at Gary, Ind., and the Spaulding Employees' Mutual Benefit Association at Binghamton, N. Y.

9. *All government hospitals in Cook County except state and federal hospitals should be administered by a single metropolitan hospital commission to be authorized by legislation and to be appointed by the Chicago city and Cook County administrations.* A disclosure of vital importance to medical care of the indigent and low-income groups is the lamentable absence of a broad, comprehensive, coordinated public hospitalization program adjusted to the needs of a total population of nearly four and one-half millions. The Committee believes that the only logical means of improving the public hospital situation in the interests of both the taxpayer and the sick is to bring all the public hospitals—excepting state and federal institutions—in the city and county under one nonpartisan metropolitan controlling board with a Medical Advisory Council and an outstanding medical administrator in charge.

10. Other hospital needs are listed below:

1. There should be a more widespread distribution geographically of facilities throughout the entire county for the care of the medically indigent, using so far as possible existing hospital and clinical facilities—by government subsidy if necessary.

2. More subsidized beds are needed for children and maternity patients, and additional beds for colored patients, patients with active tuberculosis and for nervous and mental patients.

3. More facilities should be provided for the care of chronic and incurable patients and for the treatment of patients during the long and often discouraging period of convalescence.

4. Some thirty unapproved hospitals having more than 1,200 beds should be brought up to the standard necessary to secure admission to the list of registered hospitals of the American Medical Association, and their staffs should be encouraged to have these hospitals registered.

5. Better appreciation is needed on the part of certain private hospitals of their obligations to contribute accurate statistical and financial data in standardized form to such fact-finding studies. The Committee believes that strong support of the Chicago Hospital Council's activities is one of the best means of insuring this very desirable end.

11. *The public ambulance service plan should be adopted.* The Committee believes that the plan proposed by the joint committee representing the Chicago Medical Society, the American College of Surgeons, the Chicago Council of Social Agencies and the Chicago Hospital Council should be adopted by the city of Chicago. This plan provides that the ambulances are to be purchased by the city and, after assignment to hospitals, each institution would be responsible for staffing and maintaining the vehicle and conducting the service in accordance with the rules and regulations formulated by the Emergency Ambulance Board.

12. *Nursing care now being provided for the sick in their homes.* The demand for low cost practical nurses to care for the sick in their homes is a large one. The commercial nurses' registries now try to provide nurses for this work at whatever salary is offered, and, since the amount offered is often too small to obtain a graduate nurse or even an experienced practical nurse, the resultant unmet need for low cost nursing opens a field which is being exploited by advertising correspondence schools of nursing. The promises of such schools attract students but the instruction gives them no practical experience in bedside nursing in return for their tuition. The schools soon thrust out the students as graduate practical nurses with diplomas and pins to prey on the public as cheap home nurses willing to work for less than \$15 a week. This situation is one which seems to demand that the medical profession, as well as the nursing profession, give it thoughtful consideration, with a view to legislative action to protect the public. The Committee believes that all nursing registries should keep permanent records of the types of complaints and their possible diagnoses for which they are asked to provide nursing care, and that they should be required to report to the health department all requests for nursing received by them in which there seems to be a possibility of the presence of some reportable disease.

13. *A single county health department should replace the many health departments now existing in the smaller villages and interurban districts.* This change contemplates that a full time physician with special training and experience in health organization would be in charge of the department and that it would be given a budget sufficient to provide adequate service to the area covered, which would increase as more and more

areas now having independent health officers might decide to contract with the county health department for such service.

14. *Nonresidents should be given emergency medical care services without delay and the responsibility for doing so in each area should be definitely fixed.* The present rule is that a person coming from another state to live in Cook County does not acquire a legal residence here until he has been here a year. If he comes to Cook County from another county in Illinois he must be here three months before he becomes a legal resident in Cook County, and he must have been a resident in Cook County for twelve months before he is eligible for care in the County Hospital. If a nonresident patient is so ill that he cannot be returned to his home town he may be taken care of by the County Hospital until such time as he is well enough to be transferred. A nonresident of the low income group who is ill or injured in Cook County is rarely able physically or financially to return to his place of legal residence for medical care at governmental expense. The cost of his care and that of hundreds, and even thousands, of others in similar predicaments in the course of a year becomes a matter of large total. The purpose of this recommendation is to place the responsibility for providing medical care on the local community, which is in a much better position to judge as to who shall bear the cost than is the sick, and often penniless, patient.

15. *The office of the Chicago Medical Society should include a department of medical care.* The director of this department should be a carefully selected physician of reputation and experience. There would thus be provided a place where reports of persons in immediate need of medical services which they could not secure could be received and promptly investigated with a view to their adjustment. Such a department would assist welfare agencies and other organizations and individuals desiring information about any phase of medical care and would bring to this Committee's attention specific situations and conditions which might be improved by action of the Chicago Medical Society or of other professional groups.

16. *Treatment of ambulatory relief patients in private physicians' offices will lessen the load now being borne by outpatient clinics.* Also the number of nonambulatory patients occupying free and part-pay beds in hospitals and related institutions for the care of the convalescent, chronic and incurably ill would be lessened materially and the patients themselves would receive better care if selected individuals could be treated at home under the supervision of private physicians. The Committee urges that plans for the medical care of these two groups of patients by private physicians in their private offices for ambulatory patients and in the patients' homes for those not absolutely requiring institutional care be made, thus reducing the need for more outpatient clinic facilities and for more institutional beds for the care of the chronically ill and convalescent.

17. *All welfare and relief organizations in the county should be formally advised of the Chicago Medical Society's appreciation of their efforts to provide or arrange medical care for those needing and seeking it and of the society's desire to assist in this work whenever its assistance might be possible or desired.*

18. *The large field of health services in schools should have the continuous and considered attention of the medical society.* The Committee recommends that there should be a standing committee of active and

interested physicians for this purpose, and it is hoped that it would successfully undertake the responsibility of providing progressive leadership agreeable to all concerned, including the public, parent-teacher associations and the school personnel.

19. *Helpful interest in the health services of colleges and universities should be shown by the society.* The Committee foresees the possibility not only of an increased demand in this field for the coverage of student illness by prepaid insurance of hospital costs, but also possibly for a similar method of payment to cover physicians' services. Such a plan should provide for free choice of physicians. The Committee believes that the curriculum should include serious and carefully planned instruction which will feature the criteria by which scientific advances in our knowledge concerning health may be distinguished from pseudo-advances, such as commonly characterize sales promotion efforts. These colleges and universities should understand and teach that the physician-patient relationship is both legally and professionally one between the patient and the individual practitioner of the healing art rather than one in which such a practitioner is the employee of a third party, as of a college, hospital or other corporation.

20. *Medical care services provided by industrial organizations, fraternal societies and pharmacies are of great interest to the medical profession.* The Committee believes that criticism of first aid departments which are not constantly under the supervision of physicians is justified and that such services, which amount to the practice of medicine by unlicensed practitioners, should be discouraged. The Committee feels that the further growth of the group hospitalization movement will contribute much to greater security of both employers and employees as concerns medical care, that it is very much to be desired that such insurance and all other periodic payment plans of providing any type of medical care should continue to be on a nonprofit basis, and that it would be most unfortunate if commercial insurance companies should succeed in developing this field for profit. In the field of pharmacy, the introduction of large numbers of expensive preparations which physicians and hospitals are being importuned to use in preference to the older preparations of the U. S. P. and N. F. has complicated the practice of medicine and pharmacy and the administration of hospitals by adding additional expense for the patient to all of these. This problem urgently requires mutual consideration and action on the part of physicians, pharmacists, medical schools and hospitals. To assist in its solution, every medical journal and bulletin and the rank and file of physicians themselves should support loyally, intelligently and enthusiastically the work of our Council on Pharmacy and Chemistry, and of the Council of Physical Therapy of the American Medical Association, in a somewhat similar field.

Respectfully submitted.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ALABAMA

New Jefferson Hospital.—Work has begun on the new \$2,000,000 Jefferson Hospital and nurses' home, Birmingham. The first two floors of the sixteen story building will be limestone, while the remaining exterior will be brick with light mortar. The roof will be of shingle tile. The new structure will house 575 patients. About \$900,000 of the total cost will be supplied by PWA funds. Dr. Harry Lee Jackson has been named medical adviser of the hospital to furnish technical suggestions for construction and equipment, according to the *Birmingham News*.

ARKANSAS

District Meetings.—The seventy-third semiannual meeting of the First Councilor District Medical Society was held at Tyronza, May 24. The speakers included Drs. Martin L. Cantrell, Marked Tree, on "Indications and Dosage of Sulfanilamide"; Walter C. Overstreet, Jonesboro, "Varied Uses of Sulfanilamide and Their Evaluation"; Benjamin F. Turner, Memphis, Tenn., "Reminiscence in Medicine for the Past Fifty Years"; Woodrow McD. Lamb, Paragould, "Pathologic, Clinical and Preventive Aspects of Endamoeba Histolytica Infection," and Oscar T. Cohen, Jonesboro, "Nonsurgical Treatment of the Sinuses."—At a recent meeting of the Second District Medical Society in Batesville the speakers were Drs. Ernest H. White and Samuel Phillips, both of Little Rock, on "Prenatal and Postnatal Care in Obstetrics" and "Feeding the Normal Infant" respectively.—The Ninth Councilor District Medical Society was addressed in Harrison June 6 by Drs. Albert S. Buchanan, Prescott, on "Medical Progress"; Urban J. Busiek, Springfield, Mo., "Sulfanilamide and Sulfapyridine in Pediatrics"; Guy D. Callaway, Springfield, Mo., "Diabetic Emergencies"; Paul L. Mahoney, Little Rock, "Diagnosis and Treatment of Foreign Bodies in the Food and Air Passages" and Joseph F. Shuffield, Little Rock, "Fractures of the Ankle."

CALIFORNIA

State Camp for Diabetic Children.—The University of California Medical School will establish a recreation camp for diabetic children of the state in Whitaker Forest, Tulare County, July 31-August 27. Thirty children between the ages of 7 and 16 can be accommodated for each two weeks' period. The chief source of funds for the camp is the Diabetic Society of America recently formed in San Francisco. Dr. Mary B. Olney, department of pediatrics of the university, will be in charge. Recreation and treatment facilities will be available to the extent of the university's resources in the event that it can obtain the necessary outside finances.

COLORADO

Society News.—Dr. Rudolf Schindler, Chicago, discussed gastroscopy before the Medical Society of the City and County of Denver June 6. A symposium on the surprising prevalence of animal-borne diseases in Colorado was presented before the society May 2.—At a meeting of the Crowley County Medical Society May 5 Dr. Henry A. Buchtel, Denver, discussed urology from the general practitioner's point of view.—Dr. Lee East discussed diseases of the eye before the Delta County Medical Society, Delta, April 28.—A cancer clinic was conducted before the Fremont County Medical Society in Canon City April 17 by Drs. Edwin T. Thorsness, Harold R. McKen and Osgood S. Philpott, all of Denver.—At a meeting of the Mesa County Medical Society, Grand Junction, May 16, Drs. Frank J. McDonough spoke on abortion and Richard Waldapfel on tracheotomy.—Dr. Rodney H. Jones, Denver, addressed the Northeastern Colorado County Medical Society in Sterling, April 13, on "Clinical Aspects of Hematology." The society was addressed May 11 by Drs. Charles W. Metz, Denver, on "Use of the Newer Anesthetic Agents," and Portia Lubchenko, Sterling, "Pellagra."—Dr. Carl Schwer, Pueblo, discussed "Psychopathology, the Public and the Physician" before the Pueblo County Medical Society May 16 and Dr. Julius L. Rosenbloom, May 2, "Brain Abscess."

DISTRICT OF COLUMBIA

The Davidson Lecture.—The fifth Davidson Lecture of the Medical Society of the District of Columbia will be delivered October 11. Physicians and scientists who wish to compete for the privilege of being the lecturer must submit their essays to the secretary of the society before September 1. Only persons working in the District are eligible.

GEORGIA

Dr. Kelly Resigns as Hospital Superintendent.—Dr. George Lombard Kelly, dean of the University of Georgia School of Medicine, Augusta, has resigned as superintendent of the University Hospital. Dr. Kelly will serve in an advisory capacity until September 1, when he will become medical director of the teaching facilities at the hospital, it was stated.

Public Health Meeting.—W. H. Weir, Atlanta, was named president of the Georgia Public Health Association at its annual meeting in Atlanta June 8-10 and Dr. Gordon T. Crozier, Valdosta, was reelected secretary. Among others, the following spoke:

Dr. Mark F. Boyd, malariologist of the Rockefeller Foundation, Tallahassee, Fla., Recent Advances in the Knowledge of Malaria.
Dr. Rolla E. Dyer, chief, division of infectious diseases, U. S. Public Health Service, Typhus Fever and Public Health.
Justin Andrews, Sc.D., state department of health, Acquired Immunity to Malaria.
Dr. A. Wilson Brown, state department of health, Epidemiologic Studies of Typhoid Fever in Georgia During 1938.

At the banquet Drs. John W. Oden, superintendent, Milledgeville State Hospital, spoke on "Mental Hygiene" and Felix J. Underwood, state health officer of Mississippi, Jackson, "Public Health—A Job for All."

IDAHO

Advisory Group on Industrial Medicine.—Six physicians were recently appointed by the governor to advise the industrial accident board on workmen's compensation claims arising from silicosis. They are Drs. Frank C. Gibson, Potlatch; Clifford O. Armstrong, Moscow; Willard O. Clark, Lewiston; James L. S. Stewart, Boise; Abram M. Newton, Pocatello, and Joseph N. Davis, Twin Falls.

Society News.—A symposium on asphyxia of the newborn was presented before the North Idaho District Medical Society recently by Drs. Frederick R. Fischer, James M. Nelson, Milo T. Harris and James D. Edgar, all of Spokane, Wash.—The Pocatello Medical Society was addressed May 5 by Drs. William W. Brothers on a peculiar type of fracture resulting from ski accidents which occurred while he was resident physician at Sun Valley, and Abram M. Newton, treatment of fractured arms of children.

ILLINOIS

Society News.—At a meeting of the Coles-Cumberland County Medical Society in Mattoon May 24 Dr. Meyer A. Perlstein, Chicago, spoke on "Use of Sulfapyridine in Pneumococcal Infections with Specific Reference to Pneumonia."—Dr. Everett Lee Strohl, Chicago, addressed the Aesculapian Society of the Wabash Valley in Robinson May 25 on "Surgery of the Aged."—Dr. Robert H. Graham, Aurora, was elected president of the Presbyterian Hospital Alumni Association at its annual reunion dinner in Chicago June 12.—The Henry County Medical Society was addressed at Kewanee May 25 by Drs. John A. Wolfer and Harold E. Davis, Chicago, on "Pathology and Diagnosis of Gastric and Intestinal Carcinoma" and "Indications and Use of Radium and Deep Therapy in Treatment of Carcinoma."—Dr. Willard Van Hazel, Chicago, discussed "Surgical Treatment of Pulmonary Tuberculosis" before the Marion County Medical Society at Centralia May 25.

Chicago

Health Insurance Plan Approved.—The committee on medical economics of the Chicago Medical Society has recommended the preparation of a plan for statewide voluntary health and hospital group insurance, newspapers reported June 4. The recommendations of the committee are contained in a report of nearly a year's study supervised by Dr. Herman L. Kretschmer, chairman, and Dr. William H. Walsh, director of study. The committee went on record as opposing the federal government's proposal for compulsory sickness insurance, it was reported.

Grace Abbott Dies.—Miss Grace Abbott, for many years chief of the Children's Bureau, U. S. Department of Labor, died of anemia June 19 in the Albert Merritt Billings Hospital, aged 60. Miss Abbott graduated at Grand Island College, Nebraska, and studied at the University of Nebraska and the University of Chicago. She served as director of the Immigrants' Protective League, 1908-1917; member of the faculty

of the Chicago School of Civics and Philanthropy, 1910-1917; director, child labor division of the U. S. Children's Bureau, Washington, D. C., 1917-1919; adviser, War Labor Policies Board, 1918; executive secretary, Illinois Immigrants Commission, 1920-1921; chief of the Children's Bureau, 1921-1934, and since 1934 professor of public welfare at the University of Chicago. She was president of the National Conference on Social Work in 1924.

IOWA

District Meeting.—Dr. Raymond E. Peck, Davenport, was elected president of the Iowa and Illinois Central District Medical Association at its annual meeting in Davenport May 11. Dr. Charles E. Robb, Rock Island, Ill., was chosen vice president, and Drs. James Dunn, Davenport, and Florens E. Bollaert, East Moline, Ill., were reelected secretary and treasurer respectively. The speakers included among others: Drs. Fred H. Albee, New York; James B. Eyerly, Chicago; Edward B. Tuohy, Rochester, Minn., and John A. Borghoff, Omaha.

University News.—Hans O. Haterius, Ph.D., Detroit, lectured on "Hormones of the Pituitary Gland" at the State University of Iowa College of Medicine, Iowa City, May 11, under the auspices of the University Graduate College and the Iowa chapter of the Society for Experimental Biology and Medicine.—Dr. Harry P. Smith, professor of pathology, State University of Iowa College of Medicine, has received a grant of \$1,500 from the John and Mark R. Markle Foundation for further studies in blood coagulation and hemorrhagic diseases; this grant is in addition to one of \$10,000 previously awarded for studies in this field.

LOUISIANA

Society News.—The Ouachita Parish Medical Society was addressed in Monroe recently by Drs. Eugene H. Countiss and Charles Barrett Kennedy, both of New Orleans, on "Treatment of Cervicitis" and "Secondary Infection of Fungus Dermatitis" respectively.

Cooperative Study of Cancer.—At the request of the division of infectious diseases, U. S. Public Health Service, Washington, the department of pathology and bacteriology of the Louisiana University Medical Center, New Orleans, will participate in a study of certain phases of the cancer problem now being investigated by the service. Kenneth L. Burdon, Ph.D., assistant professor of immunology and bacteriology, has been appointed as consultant in charge from the medical school. It is expected that the work will cover a period of years.

District Meetings.—At the quarterly meeting of the Second District Medical Society in La Place recently Drs. Emmett L. Irwin, New Orleans, discussed surgical phases of gallbladder disease and William W. Heyerdale, Rochester, Minn., "Retrograde Injection of the Great Saphenous Vein."—The Fourth District Medical Society was recently addressed in Shreveport by Dr. Millard F. Arbuckle, St. Louis, on bronchoscopy; Walter T. Colquitt, D.D.S., and Dr. Clarence H. Webb, "Dental Disease in an Aboriginal Group."—Dr. John H. Musser, New Orleans, discussed "Treatment of Pneumonia" before the Sixth District Medical Society recently in Baton Rouge and Dr. Charles McVea, Baton Rouge, "Infections of the Face."—A recent meeting of the Seventh District Medical Society in Crowley was addressed by Drs. Waldemar R. Metz and John T. Sanders, both of New Orleans, on "Primary Plastic Repair of Facial Injuries" and "Dysmenorrhea" respectively.

MARYLAND

Meeting of Post Mortem Examiners Commission.—The Maryland Post Mortem Examiners Commission, which was recently established under the enactment of chapter 369 of the state laws of 1930, held its first meeting at the Medical and Chirurgical Faculty, Baltimore, May 11. Under the law the commission shall consist of the professors of pathology of the schools of medicine of the University of Maryland and Johns Hopkins University, the state director of health, the commissioner of health of Baltimore and the attorney general of Maryland. A chief medical examiner and two assistants, physicians trained in pathology, will be appointed by the commission as well as a group of deputy medical examiners from lists submitted by the county medical societies for service in the counties, all to be trained in pathology. The entire group is to attend to all the medical functions now devolving on coroners and postmortem physicians in Baltimore or on coroners or justices of the peace acting as coroners throughout the state and to perform all duties imposed on them by the provisions of the new law. At the organization meeting Dr. William G. MacCallum was elected chairman of the commission, Dr. Robert H. Riley vice chairman and Dr. Huntington Williams secretary.

MICHIGAN

New Tuberculosis Unit.—Ground was broken May 8 for the new \$300,000 unit of the Detroit Tuberculosis Sanatorium, on the site of the present sanatorium at Tuxedo and Twelfth streets, Detroit. The new institution will be named after Dr. Burt R. Shurly. The addition will contain ninety beds besides operating and x-ray rooms and laboratory space for medical research. The sanatorium is financed by the annual sale of tuberculosis Christmas seals.

Advisory Council to Nurses' Board.—A medical advisory council has been organized for the state board of registration of nurses and attendants, under the amendatory act to the nurse registration law recently signed by the governor. Members of the new council include Drs. Clarence G. Clippert, Grayling; Ellery A. Oakes, Manistee, and Morley B. Beckett, health officer at Allegan; Mr. Ralph M. Hueston, superintendent of Hurley Hospital, Flint, and the Rev. Alfred F. Way, superintendent of Bronson Hospital, Kalamazoo.

Personal.—Dr. Leo G. Christian, Lansing, has been appointed a member of the Michigan Social Welfare Commission for a two year term. The commission is composed of five persons. Dr. Christian is president of the Ingham County Medical Society and a member of the House of Delegates of the American Medical Association.—Elizabeth C. Crosby, Ph.D., professor of anatomy, University of Michigan Medical School, Ann Arbor, was to leave in June for Aberdeen, Scotland, where she is to serve as guest lecturer during the coming academic year. According to the *University Hospital Bulletin*, Dr. Crosby is to continue her work on the anatomy of the nervous system while in Scotland and will assist in the development of a department in this specialty at the University of Aberdeen.

MINNESOTA

State Medical Election.—Dr. Bertram S. Adams, Hibbing, was elected president of the Minnesota State Medical Association at its annual meeting in St. Paul May 30. Drs. Carl M. Johnson, Dawson, and Archibald E. Cardle, Minneapolis, were chosen vice presidents; Benjamin B. Souster, St. Paul, secretary, and William H. Condit, Minneapolis, treasurer.

MISSISSIPPI

Society News.—The Northeast Mississippi Thirteen County Medical Society was addressed at its quarterly session at Houka June 13 by Drs. Thomas H. Blake, Jackson, on Colles fracture; Cecil E. Warde, Memphis, obstetrics; John D. Dyer, Houston, diagnosis of dyspepsias; George G. Armstrong, Houston, early treatment of eye injuries, and James T. Doster Jr., Columbus, intracranial injuries. Tribute was paid to Dr. William C. Walker, Houka, who is celebrating his eightieth birthday this year.—At a meeting of the Central Medical Society in Jackson June 6, members of the staff of the Louisiana State University Medical Center, New Orleans, presented the following program: Drs. Joseph Rigney D'Aunoy, "Lymphogranuloma Inguinale, a Problem for the South"; Henry Theodore Simon, "Facts About Fractures"; James W. Tedder, "Common Skin Diseases and Their Treatment"; Edwin A. Socola, "Therapy of the Diarrheas in Early Life"; Edgar Hull, "Remediable Factors in Heart Disease"; Hugh T. Beacham, "Consideration of Hematuria with Special Reference to the Painless Type"; Peter Graffagnino, "Treatment of Dysfunctional Disorders of Menstruation"; Rupert E. Arnell, "Bleeding in the Last Trimester of Pregnancy," and Urban Maes, "Modern Concepts of Intestinal Obstruction."

NEW HAMPSHIRE

State Medical Election.—Dr. James B. Woodman, Franklin, was elected president of the New Hampshire Medical Society at the annual meeting, June 8-9, in Manchester; Dr. Ezra A. Jones, Manchester, vice president, and Dr. Cleaton R. Metcalf, Concord, reelected secretary.

NEW YORK

Centennial of Albany Medical College.—The one hundredth anniversary of Albany Medical College, Albany, was celebrated at its annual commencement June 12 with Drs. James Ewing, New York, and La Salle Archambault, Albany, as guest speakers. Dr. John E. Heslin, president of the college alumni, presented a commemorative plaque on behalf of the alumni association to a member of the graduating class. At a banquet in the evening Dr. Heslin was toastmaster and the speaker was Mr. Raymond Clapper, Washington, D. C.

New York City

Society News.—The International and Spanish-Speaking Association of Physicians, Dentists and Pharmacists held its twelfth anniversary banquet at the Waldorf-Astoria Hotel May 19 with Dr. Walter Gray Crump as toastmaster. Dr. Jacob M. Gershberg is president of this society.—Drs. Haven Emerson and Ernst P. Boas addressed the Bronx County Medical Society June 21 on the Wagner health bill.

Professional Club at the Fair.—Members of the medical and allied professions visiting the New York World's Fair will have for their exclusive use the Professional Club in the Medicine and Public Health Building. The club occupies an area of 5,000 square feet and is provided with a lounge, checking facilities, rest rooms, stenographic service, telephones and other conveniences. Membership is limited to accredited members of the medical and public health and allied professions and to representatives of exhibit sponsors. Professional members pay no dues, but there is a small certification charge to cover the cost of validating credentials. The management is vested in a board of directors. The officers are Drs. James Reuling, president; Edward R. Cumiffe and Matthias Nicoll, vice presidents; Benjamin Wallace Hamilton, treasurer, and Mrs. Wilhelmina Rayne Walsh, secretary.

Convalescent Day Camp Opened.—The New York City Department of Hospitals opened on Welfare Island July 1 the Convalescent Day Camp, believed to be the first public institution of its kind in the United States. The camp occupies thirteen acres and comprises eight shelters to accommodate about 300 patients daily. An administration building includes diet kitchens and a central dining room. Admission to the camp will be for ambulatory patients between the ages of 12 and 60 and on application by hospitals, clinics and welfare agencies to the admitting physician. Dedication ceremonies were held June 29, at which Dr. Sigismund S. Goldwater, commissioner of hospitals, presided, and the speakers were Mayor La Guardia, Col. Brehon Somervell, WPA administrator for New York City, and Dr. Herbert B. Wilcox, director of the New York Academy of Medicine. The camp was built by the WPA.

American Museum of Health Launched.—Plans for the establishment of the American Museum of Health were announced at dedication ceremonies held in the Hall of Man in the Medicine and Public Health Building at the New York World's Fair June 17. The Carnegie Corporation, the Rockefeller Foundation, the Oberlaender Trust and the major life insurance companies have made possible the establishment of the museum and acquisition of most of the displays at the medicine and health building. These exhibits will be maintained and expanded in a permanent health teaching center in New York at the end of the fair. At the formal exercises dedicating the museum Dr. Livingston Farrand, president emeritus of Cornell University, presided and the speakers included Mayor La Guardia, Grover A. Whalen, president of the fair, and Drs. Edward S. Godfrey Jr., Albany, state health commissioner, John L. Rice, city health commissioner, Arthur W. Booth, Elmira, chairman of the Board of Trustees of the American Medical Association; George Baehr of the New York Academy of Medicine; Abel Wolman, Dr. Eng., Baltimore, president of the American Public Health Association; Louis I. Dublin, Ph.D., chairman of the executive committee on medicine and public health for the fair, and Homer Calver, secretary of the museum and director of the fair's health exhibit.

OHIO

Typhoid Near New Bedford.—Newspapers report an outbreak of typhoid in and near New Bedford in Tuscarawas and Coshocton counties. Three deaths had occurred up to June 10 and four persons were ill in the family of one of the victims. It was said that several other families in the vicinity had been stricken. Although the source of the epidemic had not been established at the time of the report, it was suspected that a well at the home of the first family involved was responsible.

OKLAHOMA

Southern Oklahoma Meeting.—The Southern Oklahoma Medical Association held its quarterly meeting in Sulphur June 6 under the auspices of the Murray County Medical Society. The speakers were Drs. Charles P. Bondurant, Oklahoma City, on "Cancer of the Uterus"; Arthur E. Hertzler, Halstead, Kan., "Goiter: Its Types and Treatment"; Tate Miller, Dallas, Texas, "Colitis," and Russell C. Pigford, Tulsa, "Management of Arteriosclerotic Heart Disease."

OREGON

Society News.—Dr. Brien T. King, Seattle Wash., addressed a special meeting of the Multnomah County Medical Society, Portland, June 7 on "A New and Function-Restoring Operation for Bilateral Abductor Cord Paralysis." Drs. James H. Huddleson and De Witt C. Burkes addressed the society May 17 on "Terminology in Psychiatry" and "Metrazol in Treatment of the Psychoses" respectively. Dr. John L. Haskins presented a motion picture on insulin shock treatment in dementia praecox.—Dr. Cyril N. H. Long, Sterling professor of physiologic chemistry, Yale University School of Medicine, New Haven, presented a series of lectures as the guest of the Portland Academy of Medicine May 4-6. His subjects were: "Effect of Hypophysectomy and Anterior Pituitary Extract on Metabolism"; "The Adrenal Cortex and Carbohydrate Metabolism" and "Role of the Anterior Pituitary in Certain Diseases of Metabolism, Particularly Diabetes Mellitus."—Dr. Joseph Levitin, San Francisco, addressed the Polk-Yamhill-Marion County Medical Society recently on "Ileus, Intussusception and Intestinal Obstruction."

PENNSYLVANIA

Division of Cancer Control.—The establishment of a division of cancer control in the state department of health was recently announced by Dr. John J. Shaw, Harrisburg, secretary of health. Dr. Stanley P. Reimann, Philadelphia, will be chairman and pathologist for the division and Dr. Rufus S. Reeves, Philadelphia, clinician. Addresses were made at the meeting by Drs. Reimann, Shaw and Reeves, Gov. Arthur H. James, and Drs. David W. Thomas, Lock Haven, president of the Medical Society of the State of Pennsylvania; Francis Carter Wood, New York; Ludvig Hektoen and John Collinson Jr., Washington, D. C. A general advisory committee of fifteen physicians and a specialists' consultation committee of eighteen have been appointed.

Philadelphia

Dr. Richards Succeeds Dr. Stengel.—Dr. Alfred N. Richards, professor of pharmacology, University of Pennsylvania School of Medicine and Graduate School of Medicine, has been appointed vice president of the university in charge of medical affairs to succeed the late Dr. Alfred Stengel. Dr. Richards will retain his faculty connections and will also devote part of his time to his research on physiology of the kidney. A native of New York, Dr. Richards was graduated from Yale University in 1897 and took the degree of doctor of philosophy from Columbia University in 1901. He received the honorary degree of doctor of science from the University of Pennsylvania in 1925 and an honorary medical degree in 1932. In addition, he has honorary degrees from Yale and Western Reserve universities and from the University of Edinburgh, Scotland. Dr. Richards was instructor in physiologic chemistry at Columbia from 1898 to 1904 and instructor in pharmacology for the next four years. In 1910 he was appointed professor of pharmacology at the University of Pennsylvania. During the World War he served with the scientific staff of the Medical Research Council of Great Britain and in the later months of the war was in charge of a physiologic laboratory of the A. E. F. in Chaumont, France, studying problems concerning poison gases. Many medals have been conferred on Dr. Richards, including the Kober Medal, the John Scott Medal from the city of Philadelphia, the Gold Medal of the New York Academy of Medicine, the William Wood Gerhard Medal of the Philadelphia Pathological Society, the Keyes Medal of the American Society of Genito-Urinary Surgeons and the Philadelphia Award established by Edward W. Bok for outstanding service to the city.

TEXAS

State Medical Election.—Dr. Preston Hunt, Texarkana, was named president-elect of the State Medical Association of Texas at the annual meeting in San Antonio May 11, and Dr. Leopold H. Reeves, Fort Worth, became president. Dr. Holman Taylor, Fort Worth, was re-elected secretary. The next annual session will be held in Dallas.

Society News.—At a meeting of the El Paso County Medical Society, El Paso, recently, the speakers were Drs. Isadore M. Epstein, on "Immunization in Childhood"; Franklin P. Schuster, "Malignancy of the Middle Ear"; Maurice P. S. Spearman, Jacob Travis Bennett, Wickliffe R. Curtis and Simeon H. Newman, "Personal Experience with Sulfanilamide."—At a meeting of the Dallas County Medical Society,

Dallas, June 8 the speakers were Drs. Samuel A. Shelburne on "Tumors of the Heart"; Elliott Mendenhall, "Bronchiectasis," and Lawrence E. Arnold, "An Attempt to Control Fetal Weight—Preliminary Report."

VIRGINIA

Personal.—Dr. Lee Scott Barksdale, Richmond, has been appointed health officer of Hopewell.—Harvey E. Jordan, Ph.D., professor of histology and embryology, University of Virginia Department of Medicine, Charlottesville, received the "President and Visitors' Research Prizes" of the Virginia chapter of Sigma Xi recently in recognition of his research on blood cell changes during experimental nutritional deficiency anemia.—Dr. Joseph E. Barrett, recently director of the Michigan State Hospital Commission, Lansing, has been appointed clinical director of the Southwestern State Hospital, Marion. Dr. James B. Pettis, Staunton, was appointed clinical director at the Western State Hospital, Staunton, in March.—Dr. John M. Emmett, Clifton Forge, has been appointed chief surgeon of the Chesapeake and Ohio Railway Company, succeeding Dr. William T. Oppenheimer, Richmond, retired.—The Danville Academy of Medicine honored Dr. Charles W. Pritchett, Danville, with a testimonial dinner May 9 in recognition of his long service in the community.

WISCONSIN

Society News.—Dr. Albert E. Rector, Appleton, president of the State Medical Society of Wisconsin, addressed the Sheboygan County Medical Society at its annual dinner meeting May 18 at Rocky Knoll Sanatorium, Plymouth, on modern problems in medicine.—Dr. Owen H. Wangenstein, Minneapolis, addressed the Rock County Medical Society, Janesville, May 23, on "Surgical Treatment of Tuberculosis."—The Pierce-St. Croix County Medical Society held a joint meeting with pharmacists of the two counties May 18 in Hudson with Charles H. Rogers, dean, University of Minnesota College of Pharmacy, Minneapolis, as the speaker on "Interprofessional Relationships."

HAWAII

Graduate Lectures.—Dr. William S. Middleton, dean, University of Wisconsin Medical School, Madison, conducted a graduate course for general practitioners at the Queen's Hospital, Honolulu, May 8-17. His subjects included: postoperative pulmonary complications; bronchogenic carcinoma, a challenge in diagnosis and treatment; some clinical problems in allergy; the problem of so-called essential hypertension with suggestions for its management; peripheral vascular disease, differential diagnosis and treatment; the pituitary-gonadal relationships and their practical implications; the role of the liver in certain coagulative problems, and the anemias, their interpretation and treatment. He also conducted a series of clinics at the hospital.

Territorial Election and Meeting.—Dr. William T. Dunn, Lahaina, Maui, was elected president of the Hawaii Territorial Medical Association at its forty-ninth annual meeting in Honolulu May 5-7, succeeding Dr. Harry L. Arnold, Honolulu. Other new officers include: Drs. Clarence W. Trexler, Honolulu; Henry B. Yuen, Hilo; Haliburton McCoy, Puunene, and Tadao Hata, Kapoa, vice presidents; Douglas B. Bell, Honolulu, treasurer; and Francis J. Halford, Honolulu, secretary. The 1940 session will be in Lahaina, probably the first of May. The speakers on the scientific program included:

- Dr. William S. Middleton, Madison, Wis., The Treatment of Pneumococcus Pneumonia.
- Dr. Rogers Lee Hill, Honolulu, Volkmann's Ischemic Contracture in Hemophilia.
- Dr. Frederick H. Foucar, U. S. Army, Analysis of 259 Surgical Cases Coming to Autopsy.
- Dr. George M. Clough, Use of Helium.
- Dr. Ernestine V. Kandel, Use of Sulfanilamide and Theories Concerning Its Mode of Action.
- Dr. Harold F. Moffat, Fundus Lesions in Systemic Disease.
- Dr. Henry C. Gotshalk, Actinomycosis in Hawaii.
- Dr. Louis H. Roddis, Pearl Harbor, medical corps, U. S. Navy, Botanical Characteristics of Some Pollens of Hawaii in Relation to Allergy.
- Dr. William John Holmes, Modern Trends in Cataract Surgery.
- Dr. May A. Borquist, Child Health.
- Dr. Lucius F. Badger, Epidemiologic Features of Leprosy in Hawaii.
- Dr. Ralph B. Cloward, Etiology, Pathology and Surgical Treatment of Low Back Pain and Sciatica.
- Dr. Jesse W. Smith, Deep X-Ray Therapy.
- Dr. Nils P. Larsen, George P. Pritchard, D.D.S., and Dr. Charles L. Wilbar Jr., Diet in Relation to Tooth Decay.
- Dr. Edwin E. McNeil, Hypochondriasis.
- Dr. Robert N. Perlstein, Epidemiologic Study of Tuberculous Families in Hawaii.

GENERAL

Figures on Alien Physicians.—Records of the U. S. Department of Labor show that 776 alien physicians entered the United States for permanent residence from July 1 to Dec. 31, 1938, and 324 from January 1 to March 31 of this year. Of the 1938 group the following countries were represented: Czechoslovakia 31; France 16; Germany 520; Great Britain 7; Hungary 17; Italy 30; Switzerland 22; other countries of Europe 51; Canada 45; Cuba 4; Asia 20, and other countries 13.

Incidence of Poliomyelitis Low in 1938.—The U. S. Public Health Service recently reported that the number of cases of poliomyelitis reported during 1938, 1,712, was the lowest since 1915. The highest rate was in Washington, D. C., 4.3 per hundred thousand of population. South Dakota was second with a rate of 4. Nevada reported no cases, New Hampshire and Wyoming one each. There were fifty-seven counties reporting cases in 1938 that had not reported any in the previous five-year period. Figures on the number of deaths were not available at the time of the report.

Special Society Elections.—Dr. Armin V. St. George, New York, was chosen president-elect of the American Society of Clinical Pathologists at the annual meeting in St. Louis and Dr. Leonard W. Larson, Bismarck, N. D., became president. Dr. Charles L. Klenk, St. Louis, was elected vice president and Dr. Alfred S. Giordano, South Bend, Ind., reelected secretary.—Dr. John H. Peck, Oakdale, Iowa, was named president-elect of the American College of Chest Physicians at the annual meeting in St. Louis in May. Drs. Benjamin Goldberg, Chicago, and J. Winthrop Peabody, Washington, D. C., were elected vice presidents and Dr. Robert B. Homan Jr., El Paso, Texas, secretary. Dr. Ralph C. Matson, Portland, Ore., is president for the coming year.—Dr. Elmer L. Sevringhaus, Madison, Wis., was named president-elect of the Association for the Study of Internal Secretions at the annual meeting in St. Louis in May and Philip E. Smith, Ph.D., New York, became president. Dr. Maximilian A. Goldzieher, New York, was elected vice president and Dr. Eberle Kost Shelton, Los Angeles, was reelected secretary.—Dr. Irvin Abell, Louisville, Ky., was elected president of the American Gastro-Enterological Association at the annual meeting in Atlantic City May 1-2. Drs. Andrew C. Ivy, Chicago, and Russell S. Boles, Philadelphia, were elected vice presidents and Dr. Albert F. R. Andresen, Brooklyn, secretary. The next annual meeting will be in Atlantic City June 10-11, 1940.—Dr. J. Bayard Clark, New York, was elected president of the American Association of Genito-Urinary Surgeons at the annual meeting in Williamsburg, Va., May 24-26; Dr. Montague L. Boyd, Atlanta, was elected vice president and Dr. Charles C. Higgins, Cleveland, secretary.—Dr. Horace Newhart, Minneapolis, was elected president of the American Otolological Society at the annual meeting in New York May 22-23, and Dr. Thomas J. Harris, New York, secretary.

Government Services

New Cancer Building Dedicated

The laying of the cornerstone and the dedication of the new National Cancer Institute at Bethesda, Md., took place with appropriate ceremonies June 24. Senator Homer T. Bone, Washington, co-author of the National Cancer Institute Act of 1937, was the principal speaker. The new cancer building is located at the National Institute of Health Center on the Rockville Pike near Bethesda. The 15 acre site was donated by Mr. and Mrs. Luke I. Wilson and adjoins the officers' living quarters and other buildings of the institute. The center will provide facilities for eighty scientists, research technicians and administrative officers. The \$750,000 building consists of three floors and two basements and will be fully equipped with up-to-date laboratory apparatus and research materials. It is expected that the unit will be completed in September and at that time the scientists now stationed at Gibbs Memorial Laboratory in Cambridge, Mass., and the staff members who are now located at the old institute building, Twenty-Fifth and E streets, Washington, will be transferred to the new quarters in Bethesda. The work of the institute will be administered by Dr. Lewis R. Thompson, director of the National Institute of Health; Carl Voegtlin, Ph.D., chief of the cancer institute; Dr. Roscoe R. Spencer, executive assistant, and Dr. Ludvig Hektoen, executive director of the National Advisory Cancer Council.

Foreign Letters

PARIS

(From Our Regular Correspondent)

June 12, 1939.

Foreigners in France

The majority of French physicians can be mobilized and will find their place in the army in case of war. This is not a bright outlook, for, during the last war, next to the infantry the medical service showed the greatest death rate. Many physicians are exempted from military service on account of their age, and they together with the women physicians will give their attention to the civil population menaced by aerial warfare. The French law provides for the enlistment of all persons who can be of service to the defense of the country, within the conditions laid down by the military authority; even foreigners residing in France may be enlisted. Recent laws have abolished, as to military service, the privileges foreign physicians formerly held. France is a country of immigration; 380,831 foreigners came to France in 1851; however, this figure includes tourists. The number of immigrants coming to France to earn a living was of little importance up to 1920, but it has been estimated that there are now three and a half million foreigners settled in France. Faivre, in the *Revue médicale de France*, points out that there is no efficacious medical control at the frontiers. About 20 per cent of those admitted to mental hospitals in 1935 were foreigners; more than 10 per cent of the patients admitted to French hospitals are foreigners. Three-fold control should be exercised: the first in the country of origin, the second at the frontiers, the third in France during the first years of stay. Immigration, if it increases suddenly, is similar to a massive blood transfusion, for which the donor has to be wisely chosen. It is difficult to maintain a French "race," but there is indisputably a French "nation," the "qualities" of which deteriorate with the admixture of ill adapted foreign blood. In one large jail in Paris, on the average, 30 per cent of the inmates are foreigners, a figure far too large in proportion to the percentage of foreign population: for one French prisoner there are three foreign prisoners. The poor people migrating to France are often of a most backward type, which explains their being diseased, insane or unfit.

War Surgery in Spain

Lardennois, in a lecture before the Union Franco-Italo-Américaine, attempted to point out lessons learned in the Spanish war. The conditions under which the Spanish medical staff worked on both sides were hard and yet it pulled through honorably. About 20 per cent of the men hit in battle die on the field or soon after removal. The rest are menaced not directly by the projectiles but by the complications that arise, especially hemorrhage and infection. It is necessary to act with the greatest speed, especially against the streptococcus. Against gas gangrene, surgical treatment remains the most effective. The bold attempts at primary suture after thorough cleansing of the wound have not been satisfactory. The preservation of quantities of blood before a battle appears to have been well done by the military physicians in Spain. The anesthetic best adapted to war surgery seemed to be evipal soluble (the sodium salt of *n*-methyl-cyclohexamyl-methyl barbituric acid). Organization of the medical department so as to distribute the wounded that they may all find in the shortest time a surgeon to dress their wounds or to operate on them was the most difficult part to regulate in Spain.

Lardennois finished his lecture by discussing the recently proposed procedure of scant dressings under a plaster cover. It consists in rapidly cleansing the wound and enclosing it at once in a plaster dressing, which is removed several weeks later. This occluding plaster is supposed to favor leukocytosis and phagocytosis and provide immobilization; under it the local

pu is supposed to modify itself and the epidermization is supposed to become accelerated. As it is opened toward the second month it contains abundant suppuration, under which the wound is in a fair way of cicatrizing. The Spanish surgeons were satisfied with this method; however, the French surgeons who saw the men discharged from the Spanish hospitals cannot give their approval.

Meeting of Climatologists

The Société de climatologie et d'hydrologie médicales of Paris held a formal meeting in March at which ionization of the air and the symptomatology of gout were the main topics discussed. The latter discussion brought forth much argument, which shows that no agreement has been reached on the exact nature of this polymorphic disease. Cattier pointed out that various influences (soil, smoke, fog or wind) can make the ionization of the air vastly different in adjacent and otherwise similar climates. It is desirable that all climatic stations be able to carry out regularly determinations of the ionization. Uzan pointed out that artificially produced ions differ from natural ions in size, weight, charge, motility and especially in their number.

BERLIN

(From Our Regular Correspondent)

June 1, 1939.

Education of Physicians for Military Service

Physicians of the army, navy and military aeronautics are educated in a special institution which was founded as early as 1795. Since 1895 it has been called the Emperor William Academy. It can point to such distinguished men as Helmholtz, Virchow, Löffler, Nothnagel, Leyden and Behring as its graduates. In 1910 addition was made to the building, providing student quarters and ample room for scientific divisions, laboratories and collections. After the World War the academy had to be closed and the building was used by the department of labor. After Germany asserted its rights to military defense, the Emperor William Academy was reopened Oct. 1, 1934, and given the name Academy of Military Physicians. Now the academy trains also the medical personnel of the navy and aviation in addition to that of the army. It also serves the purposes of scientific research in the military health service. A research staff has been organized with the following divisions: general and military pathology, general and military hygiene, general pharmacology and military toxicology, tropical medicines and testing bureau for alcohol in the blood. It includes a library of 250,000 volumes, regarded as the largest collection of medical books in Europe. In the same building is the medical research bureau of aviation. Students also receive special training that concerns their subsequent activity as military physicians; that is, besides the general medical courses for which they enroll. Like the other medical students in the medical department of the University of Berlin they must attend lecture courses in military hygiene, military pathology, military physiology, military psychology and war surgery. The curriculum requires six months of labor conscription and six months of training in the infantry (they continue regularly to return to their troop in vacation time to make sure of a thorough and permanent training). They likewise receive during vacation different military assignments; e.g., to the army hospitals so they may learn to nurse the sick and wounded, and to a riding and sports division. In their senior year they are assigned during vacation time to clinics and hospitals as assistants.

Every class of students is subject to a staff surgeon, a middle-aged military physician who supervises their life and studies and acts as their counselor. He forms the official connection between the respective class and the commanding officer of the academy, a surgeon general. He is also in close contact with the teaching staff of the medical department in which the students are enrolled.

Before the World War and until the Emperor William Academy was closed after the war, no tuition was charged at the

academy. The students had only to obligate themselves to serve a definite number of years as military physicians. There is still no charge for room and board. Assistance for the purchase of books and pay corresponding to rank are also still offered, but the other expenses connected with his studies, examination and uniform must be borne by the student.

Regimentation of Medical Students

The report on regimentation of medical students (*THE JOURNAL*, April 8) mentioned the shortening of the curriculum from eleven to ten semesters. The departments concerned have now set up a program, assigning to each semester the lectures and courses planned. Students are not compelled to conduct their studies according to the proposed curriculum but are strongly advised to do so—which is tantamount to compulsion. A curriculum has never heretofore officially been elaborated and published. The curriculum reveals clearly what will be expected of the German physician in the future. The medical student is not obliged to complete his studies at the same university. However, he is now officially advised to spend the last two semesters at the university at which he intends to take his final examinations.

Of interest also is an investigation of the cost of medical studies made officially by the national socialist party in connection with the new curriculum and the reduction of the medical training period. The expenses incurred by medical students are study fees, books, instruments, examination fees and the cost of living. Study fees amount on the average to 210 marks per semester, about 2,100 marks for the complete training. (The value of the mark is about 40 cents.) Books for the first four semesters cost about 120 marks, dissecting case about 20 marks. The fees for the two examinations during the preclinical stage amount to 92 marks. The clinical stage of his training brings increased expenses. The most important books cost 250 marks, instruments (stethoscope, ophthalmoscope, otoscope, reflex hammer) about 50 marks. Fees for the governmental examination reach the sum of 256 marks, for the doctoral examination 250 marks. The expenses for printing the doctoral dissertation amount to about 100 marks unless it is accepted for publication in a periodical, which is rare. A summary of the expenses yields the following totals: study fees for ten semesters 2,100 marks, examinations and so on in the preclinical period 254 marks and in the clinical period 855 marks, total 3,210 marks. Living expenses for the ten semesters vary. A modest allowance requires an expenditure of at least 110 marks a month, a total of 1,100 marks for eleven months. For the five years the minimal living expenses come to 6,000 marks. The utmost minimum for the total expenses, accordingly, is about 9,200 marks. For talented students who conform to the national socialist ideals of "moral, political and intellectual adaptability" there is a possibility of financial support by the student organization of the reich. Such support is exercised by remission of study fees and by grants for living expenses and other special needs (*THE JOURNAL* January 28, p. 347).

An auxiliary fund of this kind was established on the occasion of Hitler's fiftieth birthday, April 20. A foundation of 1,000,000 marks was set aside for talented students of moderate means as a "gift of the German physicians." From the interest of this foundation, "which is to be increased annually according to needs to 50,000 marks by contributions from the physicians, talented young Germans are to receive assistance in their medical studies, especially those who have by their own effort and ability secured the right to an education apart from the prescribed preparatory course of studies." This foundation, then, is to benefit especially those who, according to the new regulations terminating the freedom of doctoring, may be admitted to medical studies, even without the usual college education, on the basis of special achievements.

AUSTRALIA

(From Our Regular Correspondent)

May 23, 1939.

Health Insurance in Australia Is Dead

As implied in a former letter, national insurance in Australia has retreated still further along its path to oblivion. The prime minister, Mr. Menzies, has officially stated that it is impossible to bring the scheme into operation on September 4, the date to which it was last postponed. Having been so strenuously opposed to the abandonment of the scheme several months ago as to force his resignation from the cabinet, Mr. Menzies no doubt feels it incumbent on him, now that he has been recalled to assume the duties of prime minister, following the death of Mr. Lyons, to attempt further to save the scheme. He has promised to ask parliament to set up a committee of members, with whom will be associated representatives of the medical profession and approved societies and the National Insurance Commission, "to see whether a practical scheme, in which all parties will cheerfully and patriotically cooperate, can be evolved." Appearance, however, are all against the continuance of national insurance. The National Insurance Commission's activities have been largely suspended, the approved societies hover in a state of uncertainty, the royal commission on doctors' remuneration has never been reconstituted since the death of its chairman and has not made a report, and so far there has been inability to arrive at a basis which would ensure cooperation from the medical profession. From this it may reasonably be concluded that national insurance in Australia, as at present conceived, is dead.

Profession Warned by New Zealand Government

National insurance, a much vexed question in Australia, has taken on a serious complexion in New Zealand. The social security act of 1938, which became operative in New Zealand April 1, 1939, makes available to every man, woman and child resident in that country certain benefits, which comprise, first, generous pensions and unemployment insurance, together with medical, hospital and maternity benefits, and the supply of medicine and appliances. Considerable powers have been included in the act to ensure adequate services in some country areas that are sparsely populated or isolated. Supplementary benefits will be introduced as opportunity offers, covering such services as specialist and consultant, radiologic and laboratory, home nursing and domestic, optical and dental. There is immediate provision for the institution of a health education campaign, and the scope of medical research is to be extended. The prime minister, Mr. Savage, has stated that the professional standard of medical men and others giving service has been safeguarded; that care has been taken to ensure that the personal relationship of a doctor with his patient is not disturbed; that all citizens are assured of the right to make a free choice of their doctors, and that every doctor will have an opportunity of participating in the service. Despite these assurances, and after the date on which the act was due to operate, the New Zealand branch of the British Medical Association has decided unanimously that the government's scheme for the provision of medical benefits under the act is inadequate and unacceptable and that its members are unable to cooperate in its administration. The members of the branch, it is officially stated, are solidly in favor of an attitude adopted previously by the association—complete opposition to the present scheme, which offers all the people part or limited medical service as against the association's strongly held view that a free and complete service should be provided only for those unable to provide it for themselves. Of a possible 750, only twenty-two doctors in New Zealand have accepted contracts with the government to provide services under the social security act. In reply to the decision of the British Medical Association branch, the prime minister has stated that the government in introducing this

legislation had complied with the wishes of the people. Last year a general election was won almost entirely on the question of social security, the government being returned with an overwhelming majority. The government, therefore, would make the best arrangements possible to give effect to those wishes. The minister for health in New Zealand has stated that, if the medical profession under the leadership of the British Medical Association is determined to persist in its opposition, the government will have no option but to alter the whole basis of service and proceed reluctantly with the establishment of a state medical service to administer the benefits of the social security act. It was recognized that a state medical service would cause considerable disorganization among the medical profession, but the government wished to make clear at this stage the inevitable result of a policy of noncooperation and opposition.

The waters are troubled. The scheme has officially commenced operation, but deadlock persists between the government and the profession. At present maternity benefits are being provided by twenty-two practitioners and a small number of medical men attached to hospital staffs.

Blood Tests for Paternity Claims

The introduction of blood tests as evidence of parentage in contested affiliation cases has been legally provided for in New South Wales by an amendment to the child welfare bill. The clause inserted in the bill provides that, where a person against whom an affiliation order has been made denies that he is the father of the child and requests a blood test, the magistrate shall direct such a test to be carried out on the alleged father, the mother and the child; that the pathologist nominated to make the test should be a medical practitioner authorized to carry out such blood tests; that if the mother and the child or either of them did not submit to a test the complaint should be dismissed; that where an order for expenses of maintenance was in force and the mother and the child did not submit to a test, the order should be suspended until the direction of the magistrate was complied with, and that if the direction was not complied with within reasonable time the order might be discharged.

MADRID

(From Our Regular Correspondent)

May 25, 1939.

Civil War in Spain

During the late Spanish civil war all official and private positions in Madrid were monopolized by members of the government. In accordance with the Russian procedure, a position of "responsible" was created for the person in full charge of a given office. The nominations to most offices were absurd. In the General Hospital of Madrid, which is one of the best European hospitals, the person appointed as "responsible" was a Mr. Manolo, who had been locksmith to the hospital. He denounced several persons on the staff of the hospital, including physicians. Some were saved by a miracle from the "checas," and five or six were murdered. He ordered the physicians and personnel of the hospital to attend a weekly lecture delivered by himself and to give the communistic salute. The activities of the "responsible" of the San Juan de Dios Hospital were similar. He had been a laborer at the Oporto port and knew but little Spanish.

The communist-anarchist government changed the board of directors of the Colegio de Medicos. (This society is not to be confused with the Facultad de Medicina.) A dermatologist was appointed "Red dictator for the Madrid physicians." He had two ideas: to provide all physicians with a bracelet which gave free passage and prevented detention by the militiamen and to require all physicians to serve at any time they were called. The bracelets given to physicians of the Red political party had seals identifying their wearers as members of the party, whereas those given to the independent physicians had none

and the physicians wearing them were several times considered and treated as enemies. The medical profession of Madrid, next to the religious orders, suffered more than any other profession from the cruelty of the Reds. More than 150 physicians belonging to the Colegio de Medicos were murdered, and this number is exclusive of many military and municipal physicians. All physicians of military age who lived in the Red zones had to be enrolled as physicians of military sanitation. Dr. Enrique Lacalle y Pérez was one of these. He worked with enthusiasm and was given two promotions in the ranks of military sanitation. When it was found that he was not a communist he was murdered.

The communist physicians who belonged to the Popular Front were hostile to noncommunist physicians. Those who were in charge of the Beneficencia Provincial in Madrid, to which the San Juan de Dios and General Hospitals belong, met a certain day and resolved to eliminate from the hospitals any physician who was not a sincere communist. With this aim they asked the Diputacion Provincial of Madrid (a body, analogous to the French departmental council, concerned with the administration of hospitals) for the immediate expulsion of sixteen physicians and pharmacists from the hospitals, as well as a large number of interns and other members of the personnel who were regarded as opposed to the government. The members of the Diputacion Provincial gladly gave the order for their immediate expulsion. A few days later several of these physicians were murdered, including, among others, Dr. Villaverde, a neurologist who was a favorite pupil of Cajal; Dr. Sánchez Gómez, director at the department of pediatric surgery in the Beneficencia Provincial; Dr. Maestre Ibáñez and his wife, and Drs. Vergara, Gago, Jordà, Alonso Aycar and Alfredo López. Dr. José Martín Arevalo, who was also a philanthropist, was buried alive after his hands and feet had been cut off. Dr. Nicolas Ortega Jiménez killed his wife and himself while they were being taken to be murdered. Dr. Norberto Reinoso Trelles and his blind young son were also murdered.

The practicing of medicine and surgery was a constant danger. Dr. Udaeta was called to deliver the wife of a militiaman. The woman died from embolism. The husband's group went to Dr. Udaeta's home and murdered his son, a physician 24 years old, and then Dr. Udaeta himself. Dr. Gómez Ulla, general director of public health some years before, had to perform operations on wounded soldiers with the militiamen watching the operations with pistols in their hands. He was jailed for a year and so cruelly treated that now he is seriously ill in a sanatorium. Opinions of physicians in matters of public health meant nothing to the government. In order to vaccinate against typhoid and smallpox in Madrid, it was necessary to resort to the personal influence of some physician who had contact with the anarchists and the communists. Vaccination prevented the outbreak of epidemics that threatened the city, which was crowded and dirty. The physicians in the Red zones tried hard to improve the general conditions of people suffering from hunger and, frequently, from abuse and persecution. Yet the militiamen considered all physicians as being opposed to their political ideas. They were jailed because they certified the existence of disease in a case in which there was disease, because they signed a requisition card for food when there was hunger and because they authorized persons to leave or remain in Madrid according to their condition of health. All physicians to the age of 45 were enrolled as military physicians and were paid according to their rank. Those under suspicion were sent to places from which they could not return, as was the case with Lieutenant Dr. Torrijos. Those over the age of 45 were given work in the civil hospitals or in charitable institutions and their salaries were smaller than those of the female nurses and servants of the hospitals. The physicians generally were friendly to one another and to the

people during the dark days, but there were a few exceptions. The health of the people was bad, as they were surrounded by crowds, dirt, hunger, suffering, fear and the constant sight of murder.

SHORTAGE OF FOOD

Food was obtained with difficulty in Madrid during the last year of the war, being issued through the Red government according to record books containing data as to the number of persons in the family. Each member of the family was allowed approximately 100 Gm. of either lentils or rice and 100 Gm. of bread daily, 100 Gm. of sugar a month and 50 Gm. of olive oil a week. Soap could be obtained every three months, 500 Gm. for the whole family. Some fruit, potatoes and greens could be obtained every two weeks at the market, also according to the allowances showing in the family record book. At Christmas and at New Year there was an allowance of one egg for each person. Coal was provided in the amount of 10 Kg. for each family three times during the war. Milk could be obtained only for the sick, and only half a liter (1 pint) a week. This food was obtained at expensive, almost prohibitive prices. There were long lines of people awaiting their turn to buy food. They called the government "Manda Mas" ("I can do nothing but suffer through you"). Health was greatly impaired by the general conditions. The Madrileños lost an average of from 20 to 40 Kg. from their normal weight.

PREVALENCE OF DISEASE

As a consequence of the poor general and emotional conditions, many persons became sick and many died. Hemorrhages complicating cancer and pulmonary tuberculosis and cerebral hemorrhages were frequently observed. Most of the febrile diseases became complicated by tuberculosis. Patients with cerebral tuberculoma and visceral tuberculosis were seen more frequently than ever before in Madrid. Decompensated heart diseases followed in the majority of cases a fatal evolution, either because of the diminished resistance of the patient or because the proper drugs, such as digitalis, sparteine and strophanthin, were not available.

The shortage of medicines was so great that no sodium bicarbonate was available in the General Hospital, to mention only one among the many medicines in daily use of which the supply remained exhausted from the beginning of the struggle.

According to Dr. Velasco Pajares, president of the Colegio de Medicos of Madrid, a stubborn epidemic of glossal stomatitis broke out at the beginning of the national movement in March 1937, caused by the poor quality of the bread or by the lack of vitamins. Dr. Planelles, director general of public health, called a meeting of all the physicians practicing in the city, telling them that they were guilty of the unrest showed by the population regarding the hygienic conditions of Madrid and that they were working in behalf of the enemy and ordered that all those ill with glossal stomatitis be directed to the Institute of Nutrition. There they confined themselves to making notations of the treatment employed and to advise a more rational one. This, however, could not be followed, because there were no dietary resources and the institute did not furnish them.

In the spring of 1938, numerous cases of pellagra occurred. All the clinics for nervous cutaneous diseases and the San Juan de Dios Hospital were crowded. Dr. Velasco Pajares, relying on studies made in England, in the complete absence of protein food elements requested that the Institute of Nutrition furnish meat for from fifty to sixty pellagrins given assistance in a municipal clinic, only to be refused. Eighty per cent of the inhabitants of Madrid suffered from edemas, of which some were limited and others grew to enormous anasarcas. In hundreds of cases, neither albumin nor oliguresis nor chlorides were found. The diagnosis seemed to point to a diminution of the viscosity of the blood.

Trophoneurotic upsets were found in almost all persons not enjoying official employment (the latter were the only ones to eat). Alopecia areata, changes in the nails because of the lack of lime and silica and amaurosis occurred because of vitamin deficiency. In contrast with the great sufferings from hunger endured by the inhabitants of Madrid during the three years of the war, many chronically sick persons experienced an improvement in their condition, a phenomenon observed in analogous cases and not new to the medical profession. Hungry patients did not fail to exploit this fact against their physicians and against medicine. This improvement admits of a twofold explanation: 1. Spaniards habitually eat too much. Many foodstuffs basically highly spiced and fatty with acids and esters caused by rancidity were in themselves harmful. All these remained prohibited from the first week of the struggle. 2. Food allergy, susceptibility to certain substances, many of them unknown to the patient, is extraordinarily frequent. These allergies cause disorders such as colitis, modifications of the stomach and of the respiratory apparatus, dermatoses and so on, which medicine tries to combat according to the varied causes. The majority of these changes are included under the head of habitual indispositions, or sicknesses.

The epidemic of scabies which lasted from the beginning to the end of the siege of Madrid was terrible because of the frequency and persistence of the disease. Medicines necessary to combat it were lacking. Dr. Velasco Pajares proved that good results were obtained, in the absence of other resources, by the mixture of finely pulverized sulfur with vinegar (the patients bringing the vinegar, since the druggists did not have it). Pediculosis was another plague that took possession of Madrid; lice and bedbugs became masters of the population.

In spite of three winters of crowding, without heat, light and soap, there were no cases of typhus fever or epidemics of influenza. Besides the diseases previously mentioned, the most frequent were malaria, which attacked many soldiers, and syphilis. From the beginning coal was not available for heating houses and homes. In the houses that had window panes the temperature was from 43 to 45 F. during the winter of 1937-1938. In the winters of 1936-1937 and 1938-1939 the temperature within the houses was 2 degrees higher, because these winters were less inclement. In the houses in which the window panes had been broken by a riotous soldiery, the temperature was the same as outdoors. Lack of coal brought with it reduction of electrical energy. Light in the majority of the wards of Madrid was so lacking in power that one could not read at night. Without coal and without electric power, the little that had to be cooked necessitated the use of wood, which was sold at inconceivable prices.

Marriages

- GEORGE WASHINGTON PATTERSON, South Ryegate, Vt., to Miss Eleanor Mae Williams of Newbury, June 7.
LESLIE VAN DYKE DILL, Dover, Del., to Miss Catharine Elizabeth Isenhour of Durham, N. C., May 19.
THOMAS MELBOURNE IRWIN, St. Louis, to Miss Margaret Stewart of Jacksonville, Fla., May 20.
ALFRED I. FOLSOM, Dallas, Texas, to Mrs. Erma Hewett Matthews of San Antonio, March 26.
STANLEY W. HOLLENBECK, Milwaukee, to Miss Dorothy Franke of Wauwatosa, Wis., May 6.
WILLIAM LAMAR DOBES, New York, to Miss Sara Le Vert Wilson of Atlanta, Ga., June 12.
WILBUR LEACH DAVIS, Knoxville, Tenn., to Miss Gladys Sue Barr at Maryville, May 27.
CHRISTOPHER B. CARTER to Miss Rosine Hughes, both of Dallas, Texas, April 12.
HOWARD LEE WALKER to Miss Jean Fairbanks Decker, both of New York, May 13.

Deaths

DEATHS

- Philip Hoffmann** * St. Louis; Missouri Medical College, St. Louis, 1892; professor of orthopedic surgery, St. Louis University School of Medicine; member of the Clinical Orthopedic Society and the American Academy of Orthopedic Surgeons; fellow of the American College of Surgeons; served at various times and in various capacities on the staffs of St. Mary's Hospital, Bethesda Hospital and the Jewish Hospital; aged 68; died, April 21, of coronary occlusion.
- John Bernard McAneny** * Johnstown, Pa.; Medico-Chirurgical College of Philadelphia, 1896; fellow of the American College of Surgeons; past president and vice president of the Cambria County Medical Society; served at various times and in various capacities on the staffs of the Mercy Hospital and the Memorial Hospital; aged 67; died, March 21, in the Misericordia Hospital, Philadelphia, of carcinoma of the colon and coronary thrombosis.
- Albert Livingston Stavelly**, Lahaska, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1888; fellow of the American College of Surgeons; formerly clinical professor of gynecology at the George Washington University School of Medicine, Washington, D. C., and at one time superintendent of the Garfield Hospital, Washington, D. C.; aged 76; died, March 29.
- Frederic Gilbert Ritchie**, Queens Village, N. Y.; New York Homeopathic Medical College, New York, 1882; fellow of the American College of Surgeons; served during the World War; consulting ophthalmic surgeon to the New York Ophthalmic Hospital; consulting ophthalmologist to the Community Hospital, New York; Grace Hospital, New Haven, Conn.; Norwalk Hospital, and Home for the Aged, Norwalk, Conn.; aged 78; died, March 15.
- Drew Reid Handley**, Edinburg, Texas; Atlanta College of Physicians and Surgeons, 1910; member of the State Medical Association of Texas; county health officer; formerly physician at Ocala and Raiford, Fla.; served during the World War; president of the Hidalgo County Tuberculosis Association; aged 55; died suddenly, April 16, in San Antonio, of angina pectoris.
- John Milton Scanland** * Imola, Calif.; College of Physicians and Surgeons, Baltimore, 1897; member of the American Psychiatric Association; medical director and superintendent of the Napa State Hospital; formerly superintendent of the Agnew State Hospital, Agnew, and the Montana State Hospital, Warm Springs; aged 65; died, March 14, of pleurisy.
- Lesser Kauffman** * Buffalo; University of Buffalo School of Medicine, 1904; associate professor of neurology at his alma mater; member of the American Psychiatric Association and the Association for Research in Nervous and Mental Diseases; fellow of the American College of Physicians; aged 62; died, March 11, of coronary thrombosis.
- Edmund Horace Stevens**, Cambridge, Mass.; Harvard University Medical School, Boston, 1867; Civil War veteran; fellow of the American College of Surgeons; member of the New England Surgical Society; consulting surgeon to the Cambridge Hospital; aged 92; died, March 14, of lymphatic leukemia and bronchopneumonia.
- Charles Edward McGirk** * Philipsburg, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1895; past president of the Clearfield County Medical Society; fellow of the American College of Surgeons; medical director of the McGirk Sanitarium; aged 69; died, March 8, of endarteritis obliterans, uremia and nephritis.
- Frank Austin Walder**, Lockport, N. Y.; University of Buffalo School of Medicine, 1914; member of the Medical Society of the State of New York; coroner; served during the World War; on the staff of the Lockport City Hospital; aged 50; died, March 27, of cerebral hemorrhage.
- Amos Henry Stevens** * Fairmont, W. Va.; Harvard University Medical School, Boston, 1926; formerly secretary of the Marion County Medical Society; fellow of the American College of Physicians; on the staff of the Cook Hospital; aged 39; died, March 12, of chronic nephritis.
- Gladwin Anson Woodworth** * Austin, Texas; Northwestern University Medical School, Chicago, 1925; member of the Ohio State Medical Association; served during the World War; aged 45; died, March 4, in the Medical and Surgical Memorial Hospital, San Antonio.
- Horace Delos Washburn** * Beaver, Pa.; Jefferson Medical College of Philadelphia, 1914; on the staffs of the Rochester (Pa.) General Hospital, Beaver Valley General Hospital, New Brighton, and Providence Hospital, Beaver Falls; aged 51; died, March 13, of coronary occlusion.
- Albert Bogert Eckerson**, Mount Vernon, N. Y.; New York University Medical College, 1896; member of the Medical Society of the State of New York; on the staff of the Mount Vernon Hospital; aged 68; died, March 29, of heart disease, arteriosclerosis and hypertension.
- Austin Dallas Chester**, Cruger, Miss.; Memphis (Tenn.) Hospital Medical College, 1907; member of the Mississippi State Medical Association; served during the World War; aged 54; died, April 23, in the Veterans Administration Facility, Memphis, Tenn., of pneumonia.
- Morris Henry**, Helena, Ark.; Memphis (Tenn.) Hospital Medical College, 1901; member of the Arkansas Medical Society; past president of the Phillips County Medical Society; on the staff of the Helena Hospital; aged 61; died, April 17, of coronary thrombosis.
- Roy Dean Byrd**, Salem, Ore.; Willamette University Medical Department, Salem, 1906; served during the World War; superintendent of the Oregon Fairview Home; aged 58; died, April 6, in the Salem General Hospital of complications following an appendectomy.
- Harry Clement McClain**, Hustontown, Pa.; Medico-Chirurgical College of Philadelphia, 1902; member of the Medical Society of the State of Pennsylvania; county medical director; aged 58; died, March 28, as the result of an injury received in a fall.
- Jacob Washton**, Sarasota, Fla.; University and Bellevue Hospital Medical College, New York, 1913; member of the Medical Society of the State of New York; served during the World War; aged 48; died, March 18, of cerebral hemorrhage.
- Joseph Ignatius McLaughlin** * Boston; Harvard University Medical School, Boston, 1890; for many years physician to the Massachusetts State Prison Hospital, Charlestown; aged 77; died, March 26, of arteriosclerotic heart disease.
- William Harvey Means**, Percy, Pa.; Western Pennsylvania Medical College, Pittsburgh, 1900; member of the Medical Society of the State of Pennsylvania; aged 68; died, March 8, of a cerebral hemorrhage following a fall.
- John Calvin Walker**, Walkerville, Ark.; Memphis (Tenn.) Hospital Medical College, 1904; member of the Arkansas Medical Society; aged 71; died, March 24, of pneumonia following injuries received in an automobile accident.
- David Henry Roberts**, Utica, N. Y.; Bellevue Hospital Medical College, New York, 1886; past president of the Oneida County Medical Society; aged 79; on the staff of the Faxon Hospital; died, March 31, of bronchopneumonia.
- William W. Plummer**, Waterbury, Conn.; Howard University College of Medicine, Washington, D. C., 1907; aged 56; died, March 27, of carcinoma of the sigmoid with metastases to local lymph nodes and the liver.
- Horace Davenport Dow**, Maspeth, N. Y.; University of the City of New York Medical Department, New York; aged 75; died, March 16, of heart disease.
- George E. Harrison**, Candler, N. C.; Homeopathic Hospital College, Cleveland, 1883; Chattanooga (Tenn.) Medical College, 1901; aged 81; died, March 22, in Asheville of chronic nephritis and bronchopneumonia.
- Franklin Young**, Terre Haute, Ind.; Eclectic Medical Institute, Cincinnati, 1890; member of the Indiana State Medical Association; aged 72; died, March 6, in the Union Hospital of arteriosclerotic heart disease.
- Robert W. S. Pegram**, Canton, N. C.; Baltimore Medical College, 1892; served during the World War; aged 74; died, March 26, in the Veterans Administration Facility, Augusta, Ga., of myocarditis.
- Benjamin V. Wilson**, Decatur, Ga.; University of Georgia Medical Department, Augusta, 1900; member of the Georgia Association of Georgia; aged 62; died, March 19, of coronary occlusion and arteriosclerosis.
- Morton Edwin Hart** * San Francisco; University of California Medical Department, San Francisco, 1904; on the staff of the Mount Zion Hospital; aged 56; died, March 23, of coronary artery occlusion.
- Waclaw J. Wawrzynski** * Chicago; Bennett College of Eclectic Medicine and Surgery, Chicago, 1915; on the staff of the Norwegian American Hospital; aged 56; died, March 9, of ruptured gallbladder.

DEATHS

Jour. A. M. A.
July 8, 1939

Thomas Lee Aye ☉ Brackenridge, Pa.; Western Pennsylvania Medical College, Pittsburgh, 1905; on the staff of the Allegheny Valley Hospital, Tarentum; aged 61; died, March 18, of heart disease.

Chester R. Brown, San Diego, Calif.; University and Bellevue Hospital Medical College, New York, 1906; aged 63; died, March 27, in the Mercy Hospital of bronchopneumonia and bronchiectasis.

William Kennedy Neely Jr., Philadelphia; University of Pennsylvania Department of Medicine, Philadelphia, 1918; served during the World War; aged 44; died, April 1, of cirrhosis of the liver.

Samuel Case Jones, Rochester, N. Y.; Bellevue Hospital Medical College, New York, 1885; member of the Medical Society of the State of New York; aged 83; died, February 28, of lobar pneumonia.

William Carl Schoenijahn, Brooklyn; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1894; aged 66; died, March 28, in the Methodist Episcopal Hospital.

Robert Obed Rhodes, Los Angeles; Eclectic Medical Institute, Cincinnati, 1895; Kansas City (Mo.) College of Medicine and Surgery, 1917; aged 68; died, March 8, of coronary thrombosis.

Elijah Edward Johnston, Little Rock, Ark.; University of Arkansas School of Medicine, Little Rock, 1910; aged 59; died, March 20, in the Baptist Hospital of nephritis and chronic myocarditis.

George De Witt Wight ☉ Bethel, Conn.; Bellevue Hospital Medical College, New York, 1887; aged 76; died, March 20, in the Danbury (Conn.) Hospital of myocarditis and influenza.

Henry Harvard Helk ☉ Minneapolis; Minneapolis College of Physicians and Surgeons, 1902; formerly on the staff of St. Barnabas Hospital; aged 59; died, March 23, of coronary sclerosis.

Edwin Zugsmith, Pittsburgh; University of Pennsylvania Department of Medicine, Philadelphia, 1896; aged 64; died, March 15, of cerebral hemorrhage and carcinoma of the prostate.

John George Cunningham ☉ Spokane, Wash.; Rush Medical College, Chicago, 1897; on the staff of the Sacred Heart Hospital; aged 66; died, March 27, in Los Angeles of nephritis.

Sherrill Gaither Corpening, Merchantville, N. J.; Jefferson Medical College of Philadelphia, 1921; aged 40; died, April 2, in the Bellevue Hospital, Camden, of lobar pneumonia.

James William Felts, Alicia, Ark. (licensed in Arkansas in 1907); member of the Arkansas Medical Society; aged 54; died, April 2, of injuries received in an automobile accident.

Reault W. Place, Council Bluffs, Iowa; Iowa Eclectic Medical College, the Medical Department of Drake University, Des Moines, 1889; aged 80; died, March 31, of influenza.

Frans Leijonborg ☉ Liberty, Maine; College of Physicians and Surgeons, Boston, 1912; past president of the Knox County Medical Society; aged 66; died, March 30, of pneumonia.

Benjamin Wallace Roden, Haleyville, Ala. (licensed in Alabama in 1889); member of the Medical Association of the State of Alabama; aged 84; died, March 10, of influenza.

Vincent George Ahrens, St. Louis; St. Louis University School of Medicine, 1908; aged 56; died, April 2, in the Josephine Heitkamp Memorial Hospital of pneumonia.

Alexander B. McRae, Perry, Fla.; Atlanta Medical College, 1888; aged 79; died, March 7, in a hospital at Thomasville, Ga., of chronic nephritis, uremia and prostatism.

Leopold Harris, New York; New York University Medical College, 1897; on the staff of the Bronx Maternity and Woman's Hospital; aged 67; died, March 31, of heart disease.

Edward Vester Tiffany, Oakland, Calif.; University of California Medical School, San Francisco, 1894; aged 73; died, March 8, of bronchopneumonia and uremia.

Ella Tatman, Mountain Park, Okla. (licensed in Oklahoma under the Act of 1908); aged 68; died, March 13, in a hospital at Oklahoma City of carcinoma of the bladder.

George P. Strange, Egypt, Ga.; University of Georgia Medical Department, Augusta, 1898; aged 69; died, March 8, of cerebral hemorrhage and arteriosclerosis.

Aural Alva Sandy, Des Moines, Iowa; Keokuk Medical College, College of Physicians and Surgeons, 1901; aged 66; died, March 15, of cerebral hemorrhage.

George F. Tate, Harrisburg, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1893; aged 71; died, March 18, of cerebral hemorrhage.

Sallie Kennedy, Long Beach, Calif.; Sioux City (Iowa) College of Medicine, 1897; aged 72; died, March 17, in St. Mary's Hospital of chronic myocarditis.

Gustavus Charles Dohme ☉ Baltimore; Johns Hopkins University School of Medicine, Baltimore, 1902; aged 62; died, April 1, of cerebral hemorrhage.

Edward McDowell Cass, Utica, Ohio; Starling-Ohio Medical College, Columbus, 1909; served during the World War; aged 52; died, April 8, of pneumonia.

Margarete Darvas Baker, Santa Ana, Calif.; Cornell University Medical College, New York, 1911; aged 52; died, March 22, of pulmonary tuberculosis.

George Granville Southard, Denver, Colo.; Physio-Medical College of Indiana, Indianapolis, 1890; aged 72; died, March 12, of cerebral hemorrhage.

Victor Andrew Tyrasinski, Buffalo; University of Buffalo School of Medicine, 1915; police surgeon; aged 49; died, March 15, of coronary thrombosis.

William W. Fraser, Richmond, Calif.; Bennett Medical College, Chicago, 1872; aged 90; died, March 10, of chronic myocarditis and bronchopneumonia.

Samuel Russell, Macomb, Ill.; Rush Medical College, Chicago, 1881; formerly mayor of Macomb; aged 80; died, March 26, of cerebral hemorrhage.

Christian Nelson ☉ Pittsburgh; Western Pennsylvania Medical College, Pittsburgh, 1895; aged 76; died, March 28, of influenza and bronchopneumonia.

Harry H. Grosbach, Wauweta, Neb.; Eclectic Medical Institute, Cincinnati, 1885; aged 74; died, March 28, of cerebral thrombosis and arteriosclerosis.

Martin Wesley Lang, Long Beach, Calif.; McGill University Faculty of Medicine, Montreal, Que., Canada, 1888; aged 74; died, March 8.

William Henry Clancy, Burlington, Vt.; University of Vermont College of Medicine, Burlington, 1905; aged 61; died, April 9, of pneumonia.

Vernon D. Thomas ☉ Pittsburgh; Jefferson Medical College of Philadelphia, 1896; aged 67; died, March 5, of arteriosclerotic heart disease.

Daniel William Kramer, Erie, Pa.; Jefferson Medical College of Philadelphia, 1913; aged 47; died, March 14, of pulmonary tuberculosis.

Diran Balak, New York; Universität Leipzig Medizinische Fakultät, Saxony, Germany, 1905; aged 61; died, March 22, of coronary thrombosis.

Oregon W. Reese, Nashville, Tenn.; Vanderbilt University School of Medicine, Nashville, 1890; aged 81; died, March 26, of arteriosclerosis.

Thomas S. Turner, Lebanon, Ind. (licensed in Indiana in 1891); aged 75; died, March 11, of mitral insufficiency and bronchial asthma.

James A. Richmond, Denver; Denver College of Medicine, 1892; aged 73; died, March 17, of bronchopneumonia and cerebral hemorrhage.

William Levi Sears, Hemet, Calif.; Missouri Medical College, St. Louis, 1890; aged 76; died, March 22, of carcinoma of the prostate.

A. J. Lieurance, Neosho Falls, Kan. (licensed in Kansas in 1901); aged 86; died, March 3, of cerebral hemorrhage and arteriosclerosis.

Edwin Cutler Williams ☉ Chicago; Chicago Homeopathic Medical College, 1886; aged 74; died, March 9, of carcinoma of the bladder.

Jerome Thompson, Morrisonville, Ill.; Missouri Medical College, St. Louis, 1878; aged 83; died, March 7, of chronic nephritis.

Charles E. Helm, Quarryville, Pa.; Jefferson Medical College of Philadelphia, 1887; aged 80; died, March 24, of arteriosclerosis.

Elon A. Ormsby ☉ Centerville, Calif.; California Medical College, Oakland, 1896; aged 68; died, March 24, of myocarditis.

Frederick L. Smith, Stanley, Va.; University College of Medicine, Richmond, 1905; aged 60; died, March 23, of heart disease.

Justin H. Burdick, Milton, Wis.; Chicago Medical College, 1877; aged 87; was killed, April 3, in an automobile accident.

John W. Nicolay, Grayville, Ill.; American Medical College, St. Louis, 1899; aged 64; died, April 18, of heart disease.

Bureau of Investigation

BERNARR MACFADDEN FOUNDATION TAKES OVER A SANATORIUM FOR TUBERCULOSIS

In a letter addressed to a New York physician in April 1939, Bernarr Macfadden signs himself Chairman, Loomis Sanatorium. The letter states that "The Loomis Sanatorium at Liberty, New York, for treating tuberculosis, recently closed, will be reopened on May 1st under the financial guarantees made by the Bernarr Macfadden Foundation, a non profit, beneficent organization."

For years Macfadden has suggested to physicians that they send their patients to his institutions. A letter dated Oct. 21, 1907, on the stationery of "The Bernarr Macfadden Health Homes—Two at Physical Culture City, N. J.—Two at Battle Creek, Michigan" included the statement "Every patient sent us by a member of your profession will be given special attention and furthermore one-half of the regular fees charged for treatment and examination will be credited to you and you can return the amount to the patient if so desired."

During Mr. Macfadden's absence in England in 1913, an assistant general manager wrote on the stationery of "Bernarr Macfadden's Healthatorium" in Chicago to a patient in Chelvelah, Wash., stating in part: "We have had remarkable success in the treatment of cases similar to yours and therefore see no reason why we could not bring about a change in your condition which would be highly satisfactory to you in every particular."

During the same year the "Macfadden College of Physcultopathy," at the same address in Chicago as the "Healthatorium," was issuing application blanks for home study courses in "physcultopathy" for \$100.

A news item from a Missouri newspaper in 1923 noted that Bernarr Macfadden had "signalized the twenty-fifth anniversary of the inauguration of the movement to build a stronger nation by opening . . . a national health center" at Atlantic City, N. J.

In 1927 Bernarr Macfadden, on the stationery of the "American Institute for Physical Education," 1926 Broadway, New York, addressed the secretaries of state and county medical societies and departments of health, calling attention to the aims of his institute, recommending a "Physical Culture Creed."

Since 1929 the American Medical Association has been receiving inquiries about the Physical Culture Hotel at Dansville, N. Y., which was another organization founded by Bernarr Macfadden.

In 1933 Macfadden was addressing physicians on the stationery of the Bernarr Macfadden Foundation, Inc., inviting them to visit the Physical Culture Hotel at his expense and stating that he desired to give physicians and "healing experts of every nature" an opportunity to view at first hand the "extraordinary results obtained from curative physical culture."

Whether or not Mr. Macfadden had anything to do with the following organization is unknown to this Bureau, but on July 25, 1936, the Federal Trade Commission issued the following stipulation:

"The McFadden Institute of Physical Culture, Inc., 903 King St., Wilmington, Del., agrees to discontinue claims that its course in physical culture assures students that they will not have rheumatism, heart trouble, hardening of the arteries or breaking down of the body, and that such courses will make one successful, strong, magnetic and able to overcome any obstacle."

In 1936 advertisements appeared for the Macfadden-Deauville hotel and pleasure spot, Collins Avenue at 67th Street, Miami Beach, Fla. In these it was noted that there were available at this institution "Complete facilities for Bernarr Macfadden's famed Physcultopathic system of health building for those who desire it—a complete Physiotherapy department—spinal kinesotherapy treatments and special food regimens."

In the 1939 letter already mentioned, it is stated that "Doctors, physiotherapists, nurses, specialists in stimulating spinal develop-

ment, and other employees are needed. We are desirous of securing associates enthusiastically in favor of curing this disease tuberculosis through vitality-building measures which include mountain air, scientifically arranged diet, exercises that do not accelerate breathing, and artificial fever, although diathermy will be used in some cases." This letter concludes: "We would be glad to have your recommendation of those who might like to be associated with this institution under this plan, part time or full time, although applicants must be fully licensed practitioners in New York State."

As a part of the heading on the stationery of the Loomis Sanatorium, the following statement appears: "All Scientifically Approved Modern Medical Measures Combined with Bernarr Macfadden's Successful Dynamic Health Building System."

In the promotional folder of which the letter forms the first page, it is stated that Bernarr Macfadden has been "interested in the treatment of tuberculosis for more than fifty years." It is claimed that he was "threatened with this disease as a boy" and that he "cured himself through physical culture methods, but throughout all these years he has had to fight a tendency toward this terrible complaint." It is stated that "he has acquired invaluable knowledge in handling his own case in various emergencies, not counting the thousands of victims of this complaint with whom he has come in contact through his writings and through personal advice to sufferers."

To claim to be qualified to treat disease by virtue of having cured oneself is an old device used by many "patent medicine" promoters. It remained, however, for a Macfadden organization to acquire a million dollar sanatorium on a 700 acre tract and to attempt to obtain patients for that institution, at least in part, on the basis of an alleged self-cure. It is interesting to note that even though he has had all this experience in treating himself in emergencies, and though he has given advice to thousands of sufferers in his writings, he still finds it "advisable" to employ those who are fully licensed practitioners in New York for an institution located in the Empire State.

Having acquired such an institution, it remains to obtain patients. The Macfadden Foundation's method of accomplishing this is a little unusual, judging by a telegram received by the Bureau of Investigation from a state public health association ten days after the sanatorium opened. They wired: "Patients in tuberculosis sanatoria being solicited by Bernarr Macfadden's sanatorium some place in New York." Subsequently, material came to the attention of the Bureau which seemed to indicate that an offer of free admission to one individual in each state had been made in an advertisement, and that others who answered the advertisement received offers of special rates. It was noted in a special-offer letter that Dr. James H. Moore, a member of the staff of the Loomis Sanatorium for seventeen years, had been appointed chief-of-staff. Dr. Moore is a member and Fellow of the American Medical Association, and the American Medical Directory states that he specializes in tuberculosis. Regardless of the type of institution which Macfadden will maintain, there still would be no justification for inducing patients to leave sanatoriums where they are receiving excellent attention, in order to become patients at Loomis Sanatorium.

There would be little objection to Macfadden's endowing an institution for the treatment of tuberculosis, if he leaves the treatment of patients solely in the hands of physicians who are fully qualified to treat that disease and who are selected on that basis without reference to their being "enthusiastically in favor" of Macfadden's ideas of treatment.

THE JOURNAL pointed out editorially (Feb. 4, 1939) in reference to a *Liberty* magazine editorial that Macfadden "wants to cure syphilis by fasting followed by an exclusive milk diet" . . . "wants to cure gonorrhea with water treatments" . . . and "apparently thinks an exclusive grape diet will cure cancer." It is only natural to hope, therefore, that he understands tuberculosis better than he comprehends these other diseases. There is no available evidence that he has had any training in medicine or that he has any knowledge of the basic medical sciences which are prerequisites to the study of medicine. It is obvious therefore that he is not qualified to suggest treatments for those suffering from tuberculosis.

Correspondence

NEURITIS OF DIABETES MELLITUS AND AVITAMINOSIS B

To the Editor:—A communication by Dr. James S. McLester in *THE JOURNAL*, May 27, page 2113, mentions "the neuritis of diabetes mellitus, which Williams and Spies (Vitamin B, and Its Use in Medicine, New York, Macmillan Company, 1938) believe is due to vitamin B₁ deficiency." This seems to imply that Williams and Spies were the first ones to suggest the possible relationship between neuritis of diabetes and vitamin B deficiency. As a matter of fact, in a paper read at the annual session of the American Medical Association at Dallas, Texas, in 1926 (Avitaminosis in the Course of Diabetes, *THE JOURNAL*, Sept. 18, 1926, p. 901), I expressed the opinion that the neuralgic pains in the course of diabetes mellitus may be due to a disordered metabolism of nerve cells with more extensive degeneration incident to avitaminosis. This opinion was based on careful clinical observations and inquiry into the dietary habits of twenty-two diabetic patients with symptoms of paresthesia, partial loss of knee jerks and neuralgic pains, disclosing the striking feature that sixteen of them consumed food poor in vitamins, such as potato, bread and meat, and but little fresh vegetables, eggs and cream. Focal infection, alcohol, syphilis or tuberculosis as causes of neuralgic pains were ruled out, with the exception of tuberculosis in one case and syphilis in another. In the same paper are described in full the clinical and postmortem examinations of a patient with diabetes mellitus complicated by the neurologic symptoms of avitaminosis B and the eye signs suggestive of avitaminosis A. Moreover, I had given vitamin B concentrate to eight diabetic patients, as described in this paper, for treatment of associated symptoms such as constipation. In short, the relationship between neuritis of diabetes mellitus and avitaminosis B was indicated by me some twelve years prior to the publication by Williams and Spies.

MICHAEL G. WOHL, M.D., Philadelphia.

THE UNITED STATES PHARMACOPEIAL CONVENTION, INC., DECENNIAL PERIOD, 1930-1940 COMMITTEE OF REVISION OF THE UNITED STATES PHARMACOPEIA

To the Editor:—Under the Federal Food, Drug and Cosmetic Act the standards of strength, quality and purity laid down in the Pharmacopeia for the drugs and preparations that it recognizes become the legal standards for such drugs and preparations. As a consequence the manufacturer, the dispensing pharmacist and the physician have a common interest in the Pharmacopeia. The manufacturer is enabled to furnish the pharmacist with officially standardized materials, the pharmacist to dispense, with exactitude, just what the physician desires and the physician to write his prescriptions in simple terms with confidence in what the pharmacist will dispense. Without the Pharmacopeia there would be chaos. Without confidence in its sponsors the situation would be perilous.

The convention for the revision of the Pharmacopeia decides the principles under which the Pharmacopeia is to undergo revision. It also elects the officers of the convention, a board of trustees to manage administrative, legal and financial matters, and a Committee of Revision, all to serve until the next revision convention meets.

The committee of revision is composed of fifty elected members. Seventeen of these are doctors of medicine, representatives of clinical medicine, pharmacology, serology, therapeutics and so on. The other thirty-three members belong to pharmacy and the allied sciences and include representatives of

dispensing and manufacturing pharmacy, inorganic and organic chemistry, botany, pharmacognosy, biologic assay and the like.

In the past the Committee of Revision has included men of the highest rank in the several fields. That it may continue so to do it is asked that the various bodies authorized to send delegates to the convention will appoint their full quota of delegates and will select these from among those of their own people whom they know to be informed and at the same time prepared to attend the convention.

WALTER A. BASTEDO, M.D., New York.
President of the U. S. Pharmacopeia
Convention, 1930-1940.

THE EFFECTS OF THE REMOVAL OF THE THYMUS

To the Editor:—The inadequate and irrelevant quotations and misinterpretation of our reported data (*Science* 87:20 [Jan. 7] 1938; *Am. J. Roentgenol.* 39:263 [Feb.] 1938; *THE JOURNAL*, January 28, p. 290) on which Hashimoto and Freudenberger have based the major portion of their article in the April 29 issue of *THE JOURNAL* are so at variance with the actual facts that we feel a rebuttal would not be caviling.

With a single fact evident from their limited research, they have criticized our data, subjected our results to explanation never pertinent and consistently tried to interpret us away from our actual observations. From the data which they present, their article might better have taken the form of one sentence: There were no recognizable changes following thymectomy in male rats 25 days of age. With this statement we would be in complete accord, because the destruction of the thymus by x-rays in rats past 20 days of age showed none of the changes described when the thymus is destroyed in rats 2 days old.

The question of the age of the animal when the thymus is destroyed or removed is the crux of the entire experiment. Hashimoto and Freudenberger take us to task for not quoting Dorothy H. Andersen, and in their turn they quote from her review article (*Physiol. Rev.* 12:1 [Jan.] 1932) as follows: "From an analysis of this work on thymectomy, we may conclude that thymectomy does not prevent, hasten or delay the arrival of sexual maturity, and it does not prevent the occurrence of normal litters. In other words, aside from the immediate effects of the operative injury, it has not been shown that deprivation of thymus, even in early life, has any effect upon the development and function of the sexual apparatus."

We carefully studied Andersen's original articles (*J. Physiol.* 74:49 [Jan.] 207 and 212 [Feb.] 1932) and were aware that she had reported on thymectomy in rats 1 day old. But we were unable to find any clear reference to the presence or absence of changes in male animals of the day-old thymectomized series. Indeed, we are still not certain that she studied any of the males of this series. She does conclude (page 49) that:

1. Thymectomy does not affect the age or weight at which female rats reach puberty. . . . This is true even if the operation be performed at the age of 1 day.
2. Thymectomy does not affect the age at onset of oestrus cycles.
3. Thymectomy does not affect the actual or relative weight of the thyroid, adrenal or spleen.
4. Thymectomy does not affect the growth, appearance or behavior of young rats, even when the operation is performed at the age of 1 day.

These were results obtained in female rats—results identical with those we reported for female rats.

Andersen's definitely recorded negative results following thymectomy in males were all the result of thymectomy in animals at 21 days of age (page 207—again results identical with those we obtained when we destroyed the thymus by x-rays in animals 20 days or older. (Here is evident the danger inherent in quoting review articles, which cannot give all details and which lead to serious misinterpretation.)

Hashimoto and Freudenberger have objected to our method of comparing results among litter mates within litters. Actually—and our extended experience with a great many rats is responsible for the observation—comparison among litter mates is a truer standard for change than a pooled result. Litters 18 and 19, which were used for illustration, were representative of the changes observed in all the litters and were not, as was implied, especially chosen. We did not publish the individual protocols of the thirty-five litters quite simply because we believe no editor would be so obliging as to accept them.

Hashimoto and Freudenberger seem reasonably certain that we could not have avoided the thyroid in our treatment of the thymus in 2 day old rats and interpret the pituitary changes we have described in our temporary physiologic male castrates as castrate pituitaries to be dependent on the effect of stray radiation to the thyroid. They quote many authors on the pituitary changes resulting from removal of the thyroid gland and we agree that thyroidectomy cells of the pituitary may resemble the castrate cells of that organ, although Zeckwer (*Am. J. Path.* 13:985 [Nov.] 1937) has shown that they are different histologically. Thyroidectomy cells, however, appear in the pituitary only after complete ablation of the thyroid. Is it not remarkable then (1) that thyroid weight per unit body weight was the same in both our treated and control animals? (2) that histologically the thyroids of the treated and control animals were identical in appearance? and (3) that, although we treated males and females alike, all male thyroids were physiologically completely removed in spite of 1 and 2 and that all female thyroids escaped?

Furthermore, in all instances kidney weight per unit body weight was the same for treated animals and their litter mate controls.

Isolde T. Zeckwer, in her studies in rats (*Am. J. Physiol.* 121:224 [Jan.] 1938), says "It will be seen that after thyroidectomy there are significant reductions in kidney weights, increase in pituitary weights, decrease in adrenal weights in females, decrease in ovarian weights, but that changes in weights of adrenals in the male and of testes are not significant."

Compare these results with our data after destruction of the thymus in 2 day old rats. Based on organ weight-body weight ratios we have seen no reductions in kidney tissue in the treated animals, an increase in the pituitary in males but not in females, an increase in the adrenals in males but not in females, small and inconstant decreases in ovarian weight, and very striking decreases in the weights of the testes of the treated animals.

Our data already given definitely refute the destruction of the thyroid by stray radiation. The further criticism of our x-ray technic states that the extension of the head in our method of fixation of the animal brings "the pituitary gland nearly to the level of the upper reaches of the superior poles of the thyroid gland. It would seem, then, that difficulty would be encountered in shielding not only the thyroid gland but also the hypophysis itself from the large doses of roentgen rays to which the thymus was subjected." Our reported data show a very definite increase in pituitary weight in treated male animals. If we accept the statement of Hashimoto and Freudenberger, we shall be forced to believe that the "large doses of roentgen rays" actually stimulated the pituitary, which is hardly in keeping with accepted roentgen opinion.

Further, we reiterate that the center of the portal for treatment was each day determined by fluoroscopic localization over the center of the thymic shadow.

HARRY SHAY, M.D.

JACOB GERSHON-COHEN, M.D., D.Sc. (MED.)

SAMUEL S. FELS, LL.D., Philadelphia.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

PREMENSTRUAL TENSION AND POSSIBLE AVITAMINOSIS

To the Editor:—A woman aged 24 has had the following symptoms since delivery of her first child about five months ago. 1. A marked emotional irritability coupled with and exacerbated by pronounced instability of the autonomic nervous system. The latter is indicated by frequent and intense attacks of urticaria, dermatographism and heat intolerance or "hot flushes." No factor other than fatigue has been correlated with this. Intervals of extreme chilliness are also probably part of this instability. 2. Neuritic pains, consisting of a burning type of skin paresthesia, sciatic pain down the back of the right thigh and deep pain in the sole of the right foot. These are transitory in nature. 3. Muscle soreness and swelling, most constant in the posterior fold of the right axilla, the thenar eminence of the right hand and the midsole of the right foot. The swelling is visible and palpable, while the tenderness to pressure is extreme. These manifestations last from one to three days and then disappear partially, only to recur at irregular intervals. 4. Dryness of the skin, hair and nails, with brittleness of the latter two. 5. Scanty menses. Previously regular, her menses have since delivery become progressively more scanty, the last being only a slight bloody showing for about one day. There is present an extreme degree of premenstrual tension, which is only mildly alleviated by her menses. The sciatic pain is worse just before menstruation. 6. Headaches which occur at frequent intervals and are intense, giving her the sensation of a "weight pulling her head forward." 7. Variable vision, being sometimes helped by her glasses and at other times made distinctly worse by them. Headaches sometimes accompany symptoms of eye strain. Her pregnancy was marked by a severe attack of hyperemesis gravidarum requiring hospitalization. At intervals later there were skin paresthesia of a burning nature. The baby was born dead, autopsy showing only a slight hypertrophy of the right ventricle. Osmic acid preparations were negative for beriberi. The baby had presumably died from six to eight hours before delivery, as indicated by a mild degree of maceration. I had a blood count made because of the fact that at times there have been petechiae and unexplained bruises. This showed: red blood cells, 4,560,000, hemoglobin 90 per cent, color index 1.0, leukocytes 6,350 with 1 per cent young polymorphonuclears, 44 per cent segmented polymorphonuclears, 41 per cent small lymphocytes, 4 per cent large lymphocytes, 6 per cent monocytes, 3 per cent eosinophils and 1 per cent basophils. The platelet count was 169,000 per cubic millimeter. Urinalyses have been repeatedly negative. The patient has a chronic sinusitis and amygdalitis for which she is being treated, the otorhinolaryngologist not feeling that her condition warrants a tonsillectomy at this time. An infection in the episiotomy after being drained about four weeks post partum seems still to be smoldering, as evidenced by tenderness and swelling without fluctuation. Any slight cut becomes extremely painful and inflamed, so that her general resistance to infection of any sort appears to be poor. My therapy has been as follows: cod liver oil daily; vitamin B (orally and parenterally), which gives temporary relief of her neuritic pains; dicalcium phosphate, which helps the brittleness of her nails, only to have a return when discontinued; desiccated thyroid $1\frac{1}{2}$ grain (0.1 Gm.) a day, which seems to have helped her dry hair and skin but has not affected her menses or nervous symptoms. In the past week I have started estrogenic substance (amniotin) 10,000 units parenterally every other day. This is since her last menstrual period and so the effect on her menses is not known, but a slight vaginal discharge (nonspecific and nonpurulent) seems to have increased. Her nervous symptoms have not responded in any degree, though of course hardly enough time has been given yet. Please advise as to etiology and therapy.

M.D., California.

ANSWER.—It is doubtful whether any single disturbance can account for the various and bizarre symptoms and manifestations in this case. In certain respects the patient appears to be suffering from a vitamin B₁ deficiency. It is well known that there may develop in pregnancy, associated with persistent vomiting, a type of polyneuritis which is explained on a basis of vitamin B₁ deficiency and which responds to thiamin therapy. In this regard the neuritis, paresthesias, muscle pain and soreness are consistent with this diagnosis. Menstrual disturbances are also seen in this type of avitaminosis. However, there is evidence of some type of glandular dysfunction—hot flashes, heat intolerance and emotional instability, which signify ovarian failure. This, however, seems paradoxical in view of the patient's "premenstrual tension," which is assumed by some authorities to be due to an excessive amount of estrogenic substance in the blood. It is obvious that ovarian failure and excessive elaboration of estrogen are incompatible states. Another condition must be considered in this case. Cushing's disease (pituitary basophilism) or adrenal cortical hyperfunction will often result in somewhat similar symptoms, such as cutaneous changes, muscle pains, emotional instability and menstrual disturbances. Usually associated with these conditions, however,

are hypertension, sudden increase in adipose deposition, headaches with visual disturbances and cardiovascular changes.

It is recommended that a complete neurologic examination be done to determine the possibility of polyneuritis or a pituitary tumor. As an aid to diagnosis it is also recommended that thiamin chloride be administered parenterally in doses of from 50 to 100 mg. a day for a week or more in order to eliminate the question of B₁ avitaminosis.

Therapy cannot be recommended until a definite diagnosis has been made. If premenstrual tension is found to be the main factor in the patient's distressing symptoms, it is advisable to administer progesterone in the second two weeks of the menstrual period, while estrogenic therapy is indicated in ovarian failure.

SODIUM AMYTAL AS CAUSE OF DEATH

To the Editor:—The following questions are being asked in order to help determine the cause of death of a patient: 1. In death from sodium amytal poisoning is an examination of the stomach sufficient to determine whether or not death was caused by this compound? 2. If the patient died from taking 20 grains (1.3 Gm.) of sodium amytal, would this compound remain unchanged in the body some time after death and would one be able to discover it by proper analysis? In what organs would it most likely be found? Do oxidation and resulting destruction of this compound take place after death? 3. Is any amount of this compound excreted unchanged in the urine? 4. Is it reasonable to suppose that sodium amytal in a sufficient dose to kill would produce death (taken orally) within as short a time as four hours? M.D., Minnesota.

ANSWER.—1. It is never possible on the basis of the analysis of stomach contents to state definitely that death resulted from poison found therein. The poison in the stomach is only potentially toxic; death results only from the poison that has been absorbed from the gastrointestinal tract.

2. Following death from the ingestion of sodium amytal, the material remaining unabsorbed in the stomach would still be identifiable for a reasonable length of time after death. One might expect to isolate small amounts of amytal from the liver, kidney, brain and blood, but the drug itself is destroyed in the body through hydrolysis and oxidation. This destruction continues after death, particularly during the process of putrefaction. As a result of this decomposition the degradation products extracted from liver, kidney, brain and blood are amorphous gums and not specifically identifiable.

3. Amytal is not excreted unchanged in the urine. One may find gummy degradation products of amytal in the urine but not unchanged amytal itself (Shonle, H. A.; Keltch, A. K.; Kempf, G. F., and Swanson, E. E.: *J. Pharmacol. & Exper. Therap.* 49:393 [Dec.] 1933).

4. If the amount of sodium amytal taken was just sufficient to kill, one would not expect death to result as soon as four hours after the ingestion. However, if a person took an exceedingly large dose of sodium amytal it is possible that survival would not be longer than the four hour period.

STEALING IN CHILDHOOD

To the Editor:—A boy more than 6 years of age has repeatedly appropriated toys and playthings of others and then has originated most ingenious explanations, often conflicting one with the other. 1. What guide book for parents is recommended in such cases? 2. Is there cause for anxiety at the age stated when the child is unusually attractive and even precocious? 3. Give outline of methods for correction of such faults and for establishing ethical and moral control at that age. M.D., Alabama.

ANSWER.—1. The following reference guide books are recommended for the parents:

Thom, Douglas: *Everyday Problems of the Everyday Child*, New York, D. Appleton & Co., 1931.

Are You Training Your Child to Be Happy? Publication 202, U. S. Children's Bureau, 1934.

The Child from One to Six: His Care and Training, Publication 30, U. S. Dept. of Labor, Children's Bureau, 1934.

Child Management, Publication 143, U. S. Children's Bureau, 1928.

2. There is no cause for anxiety when a child who steals is attractive and mentally alert. Stealing is not at all an uncommon behavior problem in childhood and requires sympathetic individual handling of the child. One may distinguish several forms of stealing in childhood. It may be intelligent stealing when, in a careful way, the child appropriates things he badly wants or needs so as not to lead to immediate discovery. Other children do unintelligent stealing and take things with little or no caution. Often stealing may be the result of persuasion by an older child. In group stealing it is important to know whether the child is the leader (motivator) or merely a follower. Children steal a great variety of objects but money is most frequently taken, especially at home. Stealing, like lying, does not occur in infancy. The infant only slowly learns the mean-

ing of personal property and ownership. At first children believe that everything belongs to adults because the child is first given things by adults. Later he learns that the approval or disapproval of the parents, not a clear knowledge of ownership, is the guiding principle of right or wrong in this regard. It is only later that the child learns what is his own and what belongs to others. Wise parents give a child a sense of his own property rights, i. e. his toys, clothes, and so on, so that he may by analogy learn to respect the property of others. Resistance and obstinacy, if improperly managed, may result in stealing as a form of self assertion. Older children who are in the habit of getting everything they want often steal to satisfy the desire for possession. Stealing may occasionally be an expression of lax social standards in the home. Some children steal to gain attention of their parents or admiration of their playmates. Jealousy is often at the root of stealing, particularly when parents are unfair in giving one child less attention or fewer gifts than another.

3. Complete common sense knowledge of the child's personality, environment and intelligence level is the best guide to evolving a therapeutic plan. By far the largest number of children steal because of environmental disturbances. Occasionally mentally retarded children will pilfer objects, but in these instances misbehavior is caused by insufficient training or difficulty in establishing effective training.

It is best to interview the child alone, gain his confidence in a friendly, kindly manner and talk over his problems with him. He should be given a Binet-Simon intelligence test to determine his mental ability and age. Later the mother and father should be interviewed separately and their aspect of the problem evaluated concerning the stresses and strains of the domestic environment.

A small environmental modification can almost always produce the desired therapeutic effect.

HEAVY PIGMENTED BREASTS

To the Editor:—A young married woman who is not pregnant has breasts which have become heavy, pigmented and painful and which yield colostrum. She is 27 years old and had one normal child four years ago. In that pregnancy the breasts developed normally and became active during the last few weeks. Six months ago there was a miscarriage. The periods have always been normal and lasted four days with little pain and no excessive flow. The menstruation is just the same now and arrived on time this week. The present change in the breasts goes back three months, when she began to note pain such as most women do just before the monthly periods. This pain was worse just before the flow came on and was slightly relieved during the period. However, during the past two months the pain has continued all the time between the stages of her menstruation. She has been given massive doses of antuitrin-S and after two weeks of that medication by hypodermic injection she was changed to Armour's anterior pituitary liquid with hypodermic injections every other day of as much as 2 cc. Up until the employment of pituitary Friedman test and pelvic examination and consultation give negative results for pregnancy. The basal metabolic rate is plus 9.

Barnie R. Baker, M.D., Charleston, S. C.

ANSWER.—Growth and branching of the mammary gland trees, with possibly slight stimulation of the alveoli, are due to the action of estrogenic hormones, which are produced each month by the developing follicle and the corpus luteum of the ovary. Progesterone secreted by the corpus luteum in the presence of estrin causes development of the alveoli to a condition resembling that found during the first fifteen days of pregnancy. Each month the ducts and acinae are stimulated, which may be painful in some women, and with the retrogression of the corpus luteum and the rather sudden decrease in amount of estrogen and progesterone there may be some desquamation of epithelial cells lining the ducts, which may become distended and give rise to diffuse aching and some nodularity.

The breasts have become heavy. There is no mention of the possibility of mild obesity, which has a predilection for the breasts but it can result from stimulation. The pigmentation probably refers to the areolar areas, which may be due to estrogenic and progesterone stimulation.

The patient was given massive doses of antuitrin-S, which of course is not the true anterior pituitary gonadotropic hormone but is a product from the placenta. She was then given Armour's anterior pituitary extract, since which time there has been colostrum in the breasts. The colostrum might possibly be due to the presence of lactogenic hormone in the anterior pituitary extract given.

It is well that an effort was made to rule out pregnancy, but the possibility of extra-uterine pregnancy might be kept in mind a short while longer. The patient needs further observation. With the present information no one can definitely answer all these problems and any suggestions for treatment are conjectural.

EFFECTS OF ETHYLENE DICHLORIDE VAPORS

To the Editor:—Recently I have been called on to treat employees of a manufacturing plant for severe nausea and vomiting after exposure to ethylene dichloride vapors. I would appreciate any information with regard to the mechanism of this gas in producing nausea and vomiting. Are there more severe forms of acute poisoning and is there any possibility of chronic poisoning? Any suggestions as to prophylaxis and treatment will be appreciated.

M.D., Maryland.

ANSWER.—Wherever an exposure to ethylene dichloride vapors is provided, severe nausea and vomiting are the chief manifestations of toxic action. In the older literature ethylene dichloride is commonly rated as being from two to three times as toxic as carbon tetrachloride. More recent work casts doubt on these figures, so that ethylene dichloride is now regarded as of about the same order of toxicity as trichloroethylene. The mechanism of the production of nausea and vomiting is not clearly established. In addition to nausea and vomiting there may be evidence of irritation of the nose and eyes, dizziness, ataxia, fatty degeneration of the liver, nephritis and perivascular hemorrhages of the brain.

A good article on ethylene dichloride and its effects, entitled Toxicity of Industrial Organic Solvents, appeared in Report No. 80 of the British Medical Research Council, 1937. According to this report "A case of acute, but not very severe, symptoms after exposure to the vapor of dichloroethane was reported to the Home Office in 1932. The subject, who was employed in a dye works fitting a coil in a glycol plant, complained of vomiting, diarrhea, giddiness and drowsiness, with slight breathlessness after recovery from the attack. No chronic symptoms arising from prolonged exposure to ethylene dichloride have been reported, but Carozzi (*Rev. Path. Physiol. Trav.* vol. 12, p. 138) states that when trichloroethylene is mixed with dichloroethane . . . giddiness, trembling of the hands, disturbances of cardiac activity, somnolence and headache, only improved after changing the solvent," may occur.

Somewhat related articles are that by A. O. Gettler and Henry Siegel entitled Isolation from Human Tissues of Easily Volatile Organic Liquids and Their Identification (*Arch. Path.* 19:208 [Feb.] 1935) and that by W. P. Yant and B. G. H. Thomas entitled Toxic Effects of Ethylene Dibromide (*Pub. Health Rep.* 42:370 [Feb. 11] 1927).

A VISUAL ILLUSION

To the Editor:—A few years ago I observed a phenomenon the explanation of which appeared at first to be simple. However, after some thought and after asking for help from a professor of "Caltech" as well as a technician of an optical company, without any assured result, I am applying to you for clarification. The problem is simply this: If you park by the roadside and watch the automobiles approach you on the opposite side of the road by means of a powerful field glass, you will find that any car approaching at 45 miles an hour appears, through the glasses, to be crawling along at about 10 miles an hour. There seems to be some relation between time and space and our perceptive sense, and I am unable to get to the bottom of it. I thought I was growing old and stupid until I inquired of a few competent scientists, who were not only unaware of the fact of this phenomenon but were quite unable to furnish the answer. Possibly the fact that the automobile is kept sharply in focus and the surrounding scenery is not quite so sharply in focus may have some influence, but I do not think so.

Cecil E. Reynolds, M.D., Glendale, Calif.

ANSWER.—When riding in an automobile, speed is mentally estimated by the time relationship of passing a fixed object, whereas the mental estimation of speed of an approaching automobile is determined by the time space element between the car and a fixed object alongside the road. Refer to the accompany-

A, parked automobile; B, car approaching tree (C).

ing sketch. A passenger in automobile B estimates the speed at which he is traveling by the time required in passing the tree (C). An observer in car A estimates the speed of car B by the time space relationship between car B and the tree.

If the observer in car A uses a field glass of x power, the distance between car B and the tree is reduced to the actual distance divided by the power of the field glass. Thus the space between car B and the tree seems to be reduced to $BC \div x$.

Refer again to the sketch and insert figures for these distances and speeds:

Let distance AB be 1,000 feet.

Let distance BC be one seventh of that or, roughly, 133 feet.

A car going 45 miles an hour travels 66 feet a second, thus covering distance BC in two seconds.

A car going 10 miles an hour travels 14.6 feet a second, thus covering distance BC in 9.8 seconds or, roughly, ten seconds.

When viewed through an $8 \times$ field glass, distance BC appears to be $133 \div 8$, or 16.6 feet.

Consequently car B travels what appears to be 16.6 feet \times 2, or 33 feet, in the two seconds that it actually requires to go from B to C at 45 miles an hour; 16.6 feet a second is at the rate of 11.3 miles an hour, which is a fairly close estimate on the part of the inquirer.

To recapitulate, the apparent decrease in speed is due to the apparent decrease in distance covered in a given time when seen under magnification. This all applies only to cars coming head on. When viewed at an angle, the decrease in speed is less marked, and the greater the angle up to 90 degrees the less is the distortion in the estimation of the speed.

PTYALORRHEA AND PREGNANCY

To the Editor:—A patient after each pregnancy suffers with increased salivation, usually lasting several weeks after delivery. With her last child she has had increased salivation for more than six months. What is the assumed pathologic disorder and what treatment should be instituted for such a condition?

M.D., California.

ANSWER.—Unfortunately the cause of increased salivation either during pregnancy or after delivery is not known in most cases. Occasionally the toxemias of pregnancy are responsible. In most cases the treatment is empiric and most unsatisfactory. Sedatives such as sodium bromide and phenobarbital should be tried because sometimes they are helpful. Likewise a milk diet may be of benefit, especially in women who have toxemias of pregnancy. An examination should be made of the fluid that is excreted to make certain that it is saliva. Stander mentions the case of John G. Murray Jr., whose patient passed nearly a liter of fluid every day. Chemical examination revealed that the fluid had an acid reaction, which was due to the presence of hydrochloric acid in the same proportion as in gastric juice.

SERORESISTANT SYPHILIS

To the Editor:—A man aged 40, 6 feet (183 cm.) tall, weighing 220 pounds (99 Kg.), married at 21, the father of three children 18, 16 and 14 years of age, a civil engineer, does not know how he was ever exposed to syphilis. He never had illicit relations but in the fall of 1934 suffered somewhat from fatigue in the legs and eyes and consulted a physician. A general examination showed a 4 plus Wassermann reaction. A later spinal fluid test showed up as a 2 plus. His wife and children are negative to these tests. For four and one-half years the patient has been under almost continuous treatment. Tryparsamide, neosarsphenamine, arsphenamine, bismuth compounds, mercury rubs and potassium iodide have all been used liberally. He had eighty tryparsamide treatments. Many of his arsenical treatments have been of 0.9 Gm. A week ago I submitted his blood for test and it came back 3 plus Kahn. His pupil and patellar reflexes are normal. He seems in excellent health in spite of long treatments. What should be the further course of action? There is no history of any initial lesion. Is there a possibility of the blood and spinal tests being misleading? He is interested now in trying heat treatment. Any suggestions that you can give me will be greatly appreciated.

M.D., Washington.

ANSWER.—If this patient has had regular treatment in the amount described over such a period without serologic response, his condition would fall in the category of asymptomatic sero-resistant (or Wassermann fast) syphilis. The significance of the initial two plus Wassermann reaction in the spinal fluid is difficult to evaluate when the duration of the disease is unknown and no symptoms are present. Even though there has been no apparent evidence of progression of the disease while under observation, such a patient whose blood reaction did not respond to treatment should have the most thorough type of medical investigation to rule out the possibility of a deep seated active focus. This would mean, so far as the cardiovascular system is concerned, fluoroscopic, roentgenographic and electrocardiographic studies in addition to the usual physical examination, and so far as the central nervous system is concerned a repetition of the spinal fluid test. If late lesions are discovered by these special tests, the treatment must proceed accordingly. For purposes of complete evaluation of the type of involvement of the central nervous system, should such be present, the spinal fluid should be submitted not only to serologic testing for syphilis but also to cell count, protein determination and colloidal mastic (or gold) tests. If a spinal fluid definitely positive for syphilis of the central nervous system is obtained at this time, some form of spinal therapy, such as fever treatment, is indicated in

an individual of this age, provided his general physical condition will permit. In the absence of any definite visceral or central nervous system involvement, however, the patient may be placed on a rest interval with yearly observation, preferably for life, and no additional treatment other than perhaps a course of eight to twelve weeks of bismuth therapy once a year for the next three to five years.

PROBABLE ULCER DIATHESIS

To the Editor:—A white woman aged 37 developed signs of a duodenal ulcer of the perforating type five years ago. This was verified by x-ray examination. She was put on a modified Sippy diet and treated expectantly. In spite of rigid adherence to this regimen the patient had a perforation six months later. A laparotomy was performed, which revealed a duodenal ulcer, a diverticulum and numerous perforations. A partial resection of stomach and 5 inches of duodenum was performed. The patient was placed on a milk and cream diet with a colloidal suspension of aluminum hydroxide. In spite of this the pain continued and eighteen months later the patient had a severe hemorrhage. Her condition was such that several blood transfusions had to be administered. After subsidence of this hemorrhage she again adhered to a rigid medical regimen but, in spite of this, perforation occurred again six months later. Two months ago she suffered another hemorrhage. Roentgenograms within the past year made by a competent roentgenologist did not show any visible filling defects. The consensus was that in spite of the negative roentgenograms she must have an ulceration of the jejunum. Her Kahn and Wassermann reactions are negative. What further procedure should be employed on this case? What is the present status of larostidin? Would it be effective in this case?

M.D., Kentucky.

ANSWER.—This patient probably has an ulcer diathesis. The question is raised whether or not sufficiently radical surgery was done at the outset and, further, how any one could resect 5 inches of a duodenum without possibly taking off the ampulla of Vater. Are there any possible foci of infection which might be a factor in the recurrence of the symptoms? Have sensitization tests been done on the patient for a possible allergic factor? If these are negative and there is no other etiologic factor for the recurrence of these ulcers, a more radical resection might be done, possibly with the resection on the left vagus nerve. The status of larostidin at the present time is debatable. It is doubted whether it would be effective in this case.

OVARIES, ESTROGENS AND LIBIDO

To the Editor:—I have had a few women castrates, two in particular, whose sexual life was not influenced by the removal of their ovaries. Their sexual urge, even after the time of their menopause, seemed unimpaired. The fact that both ovaries had been removed was substantiated by the permanent amenorrhea which followed their operative procedures. What chance, if any, has a woman castrate of regaining her sexual vigor by the use of theelin and allied substances after castration? How much may be expected from gonadotropic substances given to a faltering male? Is it considered possible for a woman to have a normal sexual impulse and experience regular orgasms despite the absence of both ovaries?

M.D., Minnesota.

ANSWER.—The first two questions may be answered together. Whereas many women lose their libido after the change of life, a large proportion of them retain their sex desires after the menopause. Furthermore, a few women who were more or less frigid during their reproductive years experience libido after the change of life.

It is not known to what extent the ovaries are concerned in the development and maintenance of the sex urge, but it is certain that they are not the dominant factors. The psyche is undoubtedly much more important in the control of the libido. Therefore, removal of both ovaries in women who have been experiencing normal sex desires and reactions usually does not interfere with this part of their lives. Of course if the affection for the husband is gone there will be a waning of the sex desire, but this may also occur in women who are in the midst of their reproductive life. A considerable proportion of young women who menstruate regularly have no libido at all. The psyche and the technic of coitus have a great deal to do with this.

Estrogenic preparations occasionally stimulate sex desires in the female castrate but this is by no means a regular occurrence. Neither gonadotropic nor testicular substance has been shown conclusively to exert a beneficial effect on the man who is losing his potency. Neither is there any significant aphrodisiac effect in the normal man with these substances. It must be emphasized that the use of glandular substances for the purpose of stimulating sex urge is at present highly speculative and the wise practitioner will refrain from prescribing them in these conditions until a great deal more is learned about them and their undesirable side effects.

DYES FOR MUSKRAT FUR

To the Editor:—Can you tell me what dyes are used in the dyeing of muskrat fur into so-called mink dyed muskrat? Where can I purchase some of the dye for patch tests?

M.D., New York.

ANSWER.—The dyes used in converting muskrat skins into "mink" or "mink dyed" muskrat are usually paraphenylenediamine, para-aminophenol and metatoluenediamine; pyrogallol acid is sometimes added. These are combined in different proportions according to the color desired, the type and the condition of skin and various other factors. Every fur dyer with a plant of any size (even some small ones) has his own formula. The large fur dyeing plants have chemists who study and experiment constantly to find more stable or distinctive or more beautiful colors.

Any of these materials may be purchased from the Nyanza Color and Chemical Company, 215 Water Street, New York, or from Joseph H. Lowenstein & Sons, Inc., Morgan Avenue and Withers Street, Brooklyn. These firms specialize in fur dyes. The Nyanza Chemical Company has a branch at 549 West Randolph Street, Chicago.

It is suggested that for patch tests a dyed and also an undyed skin be used as well as the dyestuffs, because the combination of the chemicals with the hair or the pelt may possibly cause a reaction different from that caused by dyes alone or by furs alone. The skins may be bought from any dealer in furs or skins.

CYSTITIS, TRIGONITIS AND URETHRITIS

To the Editor:—A woman with frequent burning and pain on urination has evidence of pus and blood in the urine but is always relieved with a course of sulfanilamide for three or four days. After a few weeks the culture showed diplococcus gram positive catarrhalis 90 per cent, short rod bacilli colon type 10 per cent. What is the significance of this and the treatment suggested?

M.D., Ohio.

ANSWER.—The symptoms described are typical of acute attacks of basal cystitis, trigonitis and urethritis of a nonspecific nature. The fact that this is temporarily relieved by sulfanilamide further confirms this suspicion. The finding of organisms in the urine may mean that these are the responsible organisms or it may be contamination from the vagina. This observation is of absolutely no consequence unless the specimen examined is obtained by catheterization.

Urethral dilations are suggested, beginning with sounds that fit the urethra comfortably at this time and gradually increasing these sounds at intervals of a week until a maximum of at least 30 F. has been obtained. After each dilation the bladder should be emptied by catheter and instilled with 30 cc. of 5 per cent mild protein silver or a similar solution. The combination of this treatment with a short course of sulfanilamide by mouth will probably relieve this situation permanently, provided there is no immediate adjacent focus that may be responsible for reinfections. Chronic endocervicitis is frequently responsible for such conditions and therefore the cervix should be carefully investigated and treated if indicated.

LAXATIVE TO ACCOMPANY SULFANILAMIDE

To the Editor:—What cathartics can be safely given to a patient who is taking sulfanilamide? Also what drugs can be taken for the relief of pain while taking this medicine? I have given codeine without apparent ill effect.

M.D., Illinois.

ANSWER.—As far as evidence is available, laxatives such as phenolphthalein, fluidextract of cascara, magnesia magma or liquid petrolatum may be prescribed concurrently for patients who are taking sulfanilamide. It is best not to give more drastic purges such as magnesium sulfate. If any drug is indicated it must be given concurrently. For the relief of pain, morphine sulfate, codeine sulfate and barbitol or its derivatives may be prescribed.

POTASSIUM IN LIVER EXTRACTS—CHEMISTRY OF ERYTHROCYTES

To the Editor:—1. What part, if any, does potassium, as demonstrated in many liver extracts, play in pernicious anemia? 2. What chemical individuality is present in the red cells of pernicious anemia which differentiates them from the red cells of the normal person?

Charles F. Dewitz, M.D., Buffalo.

ANSWER.—1. Actively potent liver extracts without a trace of potassium have been produced. If potassium plays a part in pernicious anemia it is, up to the present time, unknown. 2. No chemical individuality has as yet been demonstrated in the red blood cells of the blood of persons with pernicious anemia.

Book Notices

Principles of Hematology with 100 Illustrative Cases. By Russell L. Haden, M.A., M.D., Chief of the Medical Division of the Cleveland Clinic, Cleveland, Ohio. Cloth. Price, \$4.50. Pp. 348, with 155 illustrations. Philadelphia: Lea & Febiger, 1939.

Many practicing physicians have expressed a desire for a concise discussion of hematology written in a simple style and language. The author apparently has anticipated their wishes, for this book answers that very need. Those procedures which are of value only to the trained hematologist are omitted, as are unusual variations in blood pictures. In spite of these purposeful deletions, the reader can profitably gain a thorough and scientific understanding of clinical hematology from this presentation. The book is complete and authoritative. It covers the usual list of subjects included in most books on hematology but differs principally in its originality of presentation. Emphasis is placed on the technic of examination and the clinical interpretations of these data. There are 168 original photomicrographs, ninety-five charts and drawings and numerous illustrative case histories to crystallize the descriptive material. The diagrammatic charts are distinctly original and should aid the practicing physician or student in visualizing concepts which might be difficult in words. The book is a distinct contribution in that it presents a very difficult but important subject in a manner which any student or physician cannot fail to understand. It is highly recommended and will undoubtedly enjoy a deserved popularity as an authoritative and concise source of practical hematologic information.

Schwangerschaftsunterbrechung aus urologischer Indikation. Von Prof. Dr. B. Ottow. Die Urologie in Einzeldarstellungen. Herausgegeben von Professor Dr. H. Boeminghaus. Boards. Price, 1.90 marks. Pp. 27. Leipzig: Georg Thieme, 1939.

This monograph deals with the urologic indications for the interruption of pregnancy. The interruption of pregnancy to prevent transmission of certain hereditary conditions was established by the laws of June 26 and July 18, 1935. In 1936 the Reichsärztekammer set up the necessary regulations. No comprehensive treatise on the indications for the interruption of pregnancy in disease of the urinary organs has heretofore been available. Although many publications, as well as the regulations, deal with indications in cases of the ordinary lesions of the urinary organs, such as nephritis, pyelitis and tuberculosis, gynecologic urology in its entirety has not been considered. The author believes that consideration should be given to the possibility of carrying the pregnancy to its end, of terminating the pregnancy by section and of instituting sterilization.

With the implantation of the fertilized ovum in the mucosa of the uterus, certain biologic changes occur in the body of the pregnant woman because of the action of various hormones. According to the author, these hormones permit the growth of the pregnant uterus as well as of the genital tract and also are responsible for the resulting diminished tone of the tract. The changes in the upper urinary tract, namely dilatation of the pelvis and ureter and the increase in bladder capacity, according to the author are due to the same phenomenon, hormonal action. These changes lead to stagnation of the urine and hence predispose to infection, the pyelitis of pregnancy, so that one of nature's activities to prepare for labor produces changes resulting in complications that may demand interruption of pregnancy. Various lesions of the urinary system are discussed in this article in great detail. Congenital malformations, such as hypospadias, epispadias and ectopia of the bladder, are never grounds for interrupting pregnancy. When these have been corrected by various plastic operations, the pregnancy if normal should go to term and delivery should be by section.

Interposition operations should always be accompanied by sterilization to prevent subsequent pregnancy. Transplantation of the ureters into the bowel for ectopia constitutes a strong relative indication for interruption, even if cases have been reported in which a normal pregnancy was terminated by delivery naturally or by cesarean section. Malformations of the ureter are no indication to interrupt pregnancy unless complica-

tions arise because of severe infection. In many cases of pelvic kidney no difficulty is experienced. When it does give trouble the pregnancy should not be interrupted but should be terminated by cesarean section. When dystopic solitary kidney is present the patient should be under careful observation during pregnancy and then delivered by section. If, however, the solitary kidney becomes the seat of disease, the pregnancy should be interrupted at once.

If bilateral polycystic disease is recognized early in pregnancy, the pregnancy should be interrupted. If it is not recognized until toward the end of the pregnancy, and if the pregnancy is going along without any great difficulty, one can carry on and wait. The delivery should be carried out in the most protective way, with forceps. In the case of solitary kidney, if there is no disease of the kidney there is no indication to interrupt the pregnancy. Should the kidney be the seat of disease, the pregnancy should be interrupted at once. The author believes that interruption should be too early rather than too late. Suprapubic fistula and fistula of the ureter are never indications for the interruption of pregnancy. Inflammatory lesions of the urinary organs as a rule do not indicate interruption of pregnancy. Pyonephrosis calls for nephrectomy. Other conditions, such as stone or tumor, call for correction and not for interruption of pregnancy.

From the monograph one gains the impression that pyelitis of pregnancy is relatively common in Germany, whereas it is relatively rare in this country. The author discusses the various routes of infection, stating that the mild infections run their course and terminate in a cure with or without treatment. The more severe infections respond to urologic treatment, ureteral drainage by catheter and pelvic lavage, so that the pregnancy can continue to term. In cases of high fever and toxic manifestations, miscarriage occurs. With severe infections it is necessary to interrupt the pregnancy (from 1 to 3 per cent). This is not the experience of American urologists. Opinions still differ as to whether or not pregnancy should be interrupted in severe infections and, if it should be interrupted, as to when. It is exceedingly difficult to differentiate between the severe infections in which pregnancy should be terminated and the severe infections in which the patient can go on to term. The problem of management is simplified if the toxic or septic manifestation occurs toward the end of the pregnancy. Here the problem does not resolve itself into interruption of pregnancy and the loss of the fetus but into interruption by cesarean section and delivery of a living child.

Hematuria calls for careful urologic diagnosis to determine the cause. The author discusses a group of cases of so-called essential hematuria. If the bleeding becomes dangerous toward the end of the pregnancy, cesarean section should be done. If hematuria occurs early in the pregnancy and urologic and medical treatment fail, interruption of pregnancy is in order.

If it is known that a woman has renal tuberculosis, she should be urged not to become pregnant. In the case of bilateral renal tuberculosis the pregnancy should be interrupted. Bladder stones are very rare during pregnancy and never should be removed by litholapaxy with pregnancy allowed to go on. If surgical operation is to be done, the author favors suprapubic operation. Stones in the ureter call for treatment and not for interruption of pregnancy. Stones in the kidney do not call for interruption of pregnancy but call for their removal, preferably after delivery. In cases of stone in a single kidney the indication for interruption is more strict. If the stone is small and the symptoms are mild, one might try to carry the pregnancy through to term. If the stone is observed early in the pregnancy, interruption is in order.

The author then discusses tumors of the urinary tract. Benign tumors such as papillomas should be removed by the cystoscopic method, preferably after delivery, unless they are causing symptoms. Malignant tumors should be removed at once. The management of a patient with a malignant tumor must be decided in each case. Early pregnancy should be interrupted so that one may treat the tumor unhampered. In the latter part of the pregnancy, especially toward the end, when a malignant tumor is found one must consider the child.

One is impressed by the frequency with which the author resorts to cesarean operation.

Artistic Anatomy. By Walter Farrington Moses. Second edition. Cloth. Price, \$3.50. Pp. 59, with 57 plates. Los Angeles, California: Borden Publishing Company, 1939.

This newly revised, augmented edition was published especially for artists. There are fifty-seven plates of anatomic drawings presenting the human skeleton and muscles. The black and white pencil drawings are anatomically accurate. The annotations on the face pages for each plate are concise and informative, giving the anatomic names of the bones and muscles with a concise description of the skeleton and the origins, insertions and actions of the muscles. The appreciation of muscle contours of the human body and their relation to the skeleton and skin is important to artists. There are drawings of the entire body in various postural attitudes and also separate drawings of the extremities, head and neck and trunk. The introduction is a complete short treatise on the anatomy of bones and joints from the topographic point of view. A complete page glossary is given at the end. Artists, physical therapists, physical educationalists and physical culturists should derive great benefit from this book.

Vitamins and Vitamin Deficiencies. By Leslie J. Harris, Ph.D., Sc.D., D.Sc., Nutritional Laboratory, Medical Research Council and University of Cambridge. Vol. 1: Introductory and Historical. Vitamin B₁ and Beri-Beri. With foreword by Sir Frederick Gowland Hopkins, O.M., F.R.C.P., F.R.S. Cloth. Price, \$2.50. Pp. 204, with 50 illustrations. Philadelphia: P. Blakiston's Son & Co., Inc., 1938.

The author is a well known authority on nutrition, and yet with characteristic modesty he states that the present volume has been written because of a need of keeping himself familiar with the growth of knowledge about the vitamins. To learn about a subject there is the Oxford way—to read all the books that have been written on it—and the Cambridge way—to write your own book. Readers will be glad that Professor Harris chose the Cambridge way. The present small volume consists of an introduction to the vitamins from the historical point of view and a discussion of vitamin B₁ and of beriberi as a vitamin deficiency disease. The features of the book are the commendable brevity with which the material is summarized, the large number of well chosen illustrations and the fairly complete bibliography. Some of the experimental results described in the literature are well summarized in the form of tabular statements. The book is extraordinarily complete for one of such small size. Perhaps its value lies in part in the fact that its material has been long digested; the author states that the original manuscript was begun six years ago, but it has necessarily been revised many times since then. In addition to the fifty illustrations there are twenty-four tables in the text. There is an adequate subject index and also an author index. The latter covers four and one-half pages of fine type, which is in itself an indication of the extent of the bibliography in each chapter. The reader must agree with the statement in the foreword by F. Gowland Hopkins that the book can be recommended to all students who desire information and those specialists who would welcome a well written summary of available facts and a satisfactory bibliography.

Studies on the Size of the Red Blood Cells Especially in Some Anemias. By Erik Mogensen. Denne Afhandling er af det lægevidenskabelige Fakultet antaget til offentlig at forsvares for den medicinske Doktorgrad, København. Cloth. Pp. 216, with 43 illustrations. Copenhagen: Ejnar Munksgaard; New York & London: Oxford University Press, 1938.

The determination of red blood cell diameters has assumed a prominent role in the classification and therapy of many anemias. The fact that the procedure serves as a guide to rational treatment has elicited clinical interest. In the first chapter the author reviews the various methods for determining the size of red cells. The next chapter is devoted to a detailed and comprehensive discussion of the Prue-Jones method, which the author employed in his study. Then follow chapters on the author's measurements in normal persons and in persons with pernicious anemia, simple anemia with achylia, the hypochromic anemia of infants, idiopathic steatorrhea, anemia in carcinoma of the stomach, diseases of the liver, leukemia, acholuric jaundice, renal disease and scurvy. Representative case histories are given as a separate chapter complementing the discussions. The last chapter is devoted to a summary of each

of the preceding chapters. The monograph is a definite contribution and can be read and understood by the novice. In spite of the literary simplicity, the author has not sacrificed any important mathematical or hematologic data. An exhaustive bibliography is available for those who wish to pursue any phase of the subject in greater detail. The work reflects a scholarly and practical study and can be profitably read by every one engaged in hematologic work.

Surgical Pathology of the Diseases of the Mouth and Jaws. By Arthur E. Hertzler, M.D., Surgeon to the Agnes Hertzler Memorial Hospital, Halstead, Kansas. Cloth. Price, \$5. Pp. 248, with 206 illustrations. Philadelphia, Montreal & London: J. P. Lippincott Company, 1938.

This is the last of a series of ten monographs written by Hertzler discussing the surgical pathology of various regions of the body. Dr. Hertzler continues to be one of the most entertaining medical authors. This volume is profusely illustrated with reproductions of photographs from clinical cases and photomicrographs of the lesions discussed. Benign and malignant lesions of the mouth, lips and tongue are briefly but adequately described. There is a short chapter on tumors of dentigerous origin for which the unfortunate synonym "mixed tumors" is used. This may give rise to some confusion, since heterologous salivary gland tumors also are referred to as "mixed tumors." There are two chapters on diseases of the nasopharynx and the larynx in which the surgical diseases are briefly described. Because, as Hertzler states in the preface, the book is written only of things he has seen and on the basis of his own experience, the text is not a complete account of the surgical pathology of these regions. However, the material presented is interestingly and often amusingly discussed and should prove of value to those treating the diseases of this region.

Uterus Masculinus: A Critical and Constructive Essay Concerning the Genitalia and Their Homologues. By J. A. Leo Magee, M.B. Cloth. Price, 5s. Pp. 95. London: H. K. Lewis & Co., Ltd., 1939.

This is a nicely bound small essay developing an erroneous idea conceived seventeen years earlier and not weighed against recent advances, to the effect that the male prostate gland is the homologue of the uterus. One seeking basic information on the uterus masculinus will need search elsewhere.

Diabetic Retinitis: Clinical Studies of 195 Cases of Retinal Changes in Diabetics. By Steen Hanum. Denne Afhandling er af det lægevidenskabelige Fakultet antaget til offentlig at forsvares for den medicinske Doktorgrad, København. Acta Ophthalmologica, Supplementum XVI. Paper. Pp. 174, with 12 illustrations. Copenhagen: Ejnar Munksgaard, 1939.

This work was submitted by Hanum as his thesis for his degree of doctor of medicine. The material was compiled from examination of patients in Copenhagen hospitals during the years 1928 to 1938. Examinations were made of 966 patients with diabetes, 195 of these having retinal lesions. Statistical data, including age, duration of the disease, sex, gravity of the diabetes and incidence of retinal manifestation are catalogued and compared with material of authorities such as Joslin, Waite and Beetham, Braun and Wagener and Wilder. The history and the ophthalmoscopic picture in diabetes are reviewed. The retinal manifestations are divided into four types: (1) exudative diabetic retinitis, (2) circinoid diabetic retinitis, (3) hemorrhagic diabetic retinitis and (4) proliferative diabetic retinitis. Sixty per cent of his 195 patients had the first type. The fourth type is considered in great detail. There were only twelve patients with this type, and Hanum believes that capillary resistance is lowered in such patients and that ascorbic acid and vitamin P (citrin) are indicated in the treatment. The cause of the retinitis is discussed under the headings of carbohydrate-metabolism, glycosuria, hyperglycemia, lipid metabolism, acetone bodies and relationship of renal factors, including hypertension and arteriosclerosis. A chapter on the pathologic anatomy of the retinitis is included. Diagnosis, therapy, the use of insulin and the prognosis in given cases conclude the dissertation. Hanum has worked out a mathematical formula as to prognosis. He concludes that (1) the greatest incidence both of diabetes and of retinitis is met in the fifth and sixth decades, (2) there is a marked relationship between the duration of diabetes and the occurrence of retinal changes and (3) the Volhard thesis "with-

out hypertension no retinitis in diabetic patients" cannot be maintained in the categorical form in which it has been set forth. Drawings, colored photographs and an excellent bibliography are included. The article in its translation from Danish is not in the best of English style but the meanings are clear. The work is of decided interest to all physicians who number diabetic persons among their patients.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Malpractice: Fracture of Tibia and Fibula; Failure to Make Roentgenograms; Absence of Callus; Expert Testimony.—One of the plaintiffs fractured the tibia and fibula of her right leg Oct. 23, 1935. When she was brought to the defendant physician he advised her removal to one of two named hospitals which had adequate facilities for the treatment of such a case. To this she demurred because of the expense. The defendant thought, however, that he could treat the fracture without using x-ray equipment, and the patient was taken to the county hospital, which was lacking in that respect. There the defendant set the fractured bones and applied a temporary plaster of paris cast. On November 11 he replaced that temporary cast with a permanent one. He furnished the plaintiff with calcium tablets to aid the process of nature in uniting the bones and then discharged her from the hospital, after warning her against placing weight or strain on the broken leg. After her discharge the patient visited the defendant weekly until December 20. On that day she informed him that roentgenograms taken by a Dr. Harlan the day before showed that the bones had not united and were out of alignment. At the defendant's insistence, a roentgenogram was made by a Dr. Brown, which showed that the bones were, according to Dr. Brown, in a "nice position as far as being opposite to each other is concerned" but were not properly united and that there was an absence of callus. The defendant then advised the plaintiff to consult a bone specialist. She did not consult the defendant after that date.

The patient and her husband sued the physician defendant for malpractice. To prove negligence they relied on the facts that he had not used an x-ray machine nor used mechanical tension on the limb and that the bones had not properly united because of a lack of callus. The trial court directed a verdict in favor of the defendant. The plaintiffs appealed to the district court of appeal, third district, California.

The action of the trial court was proper, in the opinion of the appellate court, since there was no substantial evidence to support a judgment against the defendant. It is true, said the court, that the defendant made no roentgenograms of the fracture, but he refrained from doing so because he knew its character in a general way and could feel the break and its general direction. He had advised the defendant to go to an adequately equipped hospital but she had declined to do so and went to a hospital where no x-ray equipment was available. The defendant believed that he could reduce the fracture without such equipment and apparently he did so, for Dr. Brown, who made a roentgenogram on or about December 20, testified that the bones were in nice position as far as being opposite to each other was concerned. In the opinion of the appellate court, it could not be said that failure to use an x-ray machine in the reduction of a fracture constitutes negligence under all circumstances. The necessity of employing an x-ray machine in reducing a fracture depends entirely on the circumstances of the particular case. Whether the reduction and treatment of a fractured bone without the use of an x-ray machine constitutes negligence depends on what an ordinarily skilled physician practicing in the vicinity, in the exercise of due care and professional judgment, does under like circumstances. The determination of that question depends on expert testimony.

The testimony of Dr. Brown, called as an expert witness for the plaintiffs, that there appeared to be an absence of

callus to unite the bones properly, furnished, in the opinion of the appellate court, no evidence of negligence on the part of the defendant, in the absence of expert testimony showing treatment by him in conflict with the recognized practice of other skilled physicians in the vicinity. The fact that nature failed to develop normally the callus necessary to unite the bones and that the defendant did not discover that unusual condition did not prove that he was guilty of malpractice. There was no evidence to show that any error on his part helped to prevent the normal development of callus. The only omission by the defendant, said the appellate court, of which the plaintiffs might reasonably complain was his failure to make roentgenograms at an earlier date after reducing the fracture. If he had done so, possibly he might have discovered sooner the lack of callus and have advised his patient to consult a bone specialist then. The defendant testified, however, that he had no intimation of a lack of callus until the roentgenogram was taken December 20. The omission of earlier roentgenograms was, therefore, only an error of judgment, and an error of judgment does not constitute actionable malpractice.

Over objection by the defendant, another medical expert called by the plaintiffs testified in response to a lengthy hypothetical question that it was not accepted medical practice in the community in which the patient was treated or any other community to attempt to set a broken leg without the use of x-ray apparatus and without applying traction or tension to the foot to adjust the bone. On cross-examination it was shown that this witness based his conclusions on his own judgment and not on his knowledge of the customary practice of other skilled physicians in the locality in which the case was treated; he conceded that he did not know what the practice of other physicians in that locality was. The action of the trial court, said the appellate court, in striking out the testimony of this witness, on the motion of the defendant, on the ground that the witness was not qualified to testify concerning the matter, was proper. A medical expert witness must possess the required professional knowledge, learning and skill to enable him to express an opinion and must be familiar with the methods of treatment of similar ailments by other physicians in the locality and with the knowledge and skill required in such treatment.

Objection by the defendant to a hypothetical question propounded by plaintiffs' attorney to another medical expert called by the plaintiffs was sustained by the trial court because the question did not state all the essential circumstances incident to the setting of the fractured bones and to the subsequent treatment. The chief test of the competency of a hypothetical question, said the appellate court, which seeks to elicit the professional opinion of a physician regarding the treatment of a patient is whether it is or is not a full and fair recital of all the essential evidence disclosed by the records on the particular issue which is involved. Where the question assumes facts in direct conflict with the undisputed evidence or omits material facts on which a determination of the problem depends, the hypothetical question becomes misleading and is likely to lead the witness to a false conclusion. Under such circumstances, the question should be excluded. The action of the trial court in excluding the disputed question in the present instance was sustained by the appellate court.

The action of the trial court in directing a verdict in favor of the defendant physician was sustained.—*Bickford v. Lawson* (Calif.), 81 P. (2d) 216.

Society Proceedings

COMING MEETINGS

Idaho State Medical Association, Boise, Aug. 23-26. Dr. J. N. Davis, 204 Fourth Avenue East, Twin Falls, Secretary.
National Medical Association, New York, Aug. 15-19. Dr. John T. Givens, 1108 Church St., Norfolk, Va., General Secretary.
Washington State Medical Association, Spokane, Aug. 28-30. Dr. V. W. Spickard, 1305 Fourth Ave., Seattle, Secretary.
West Virginia State Medical Association, White Sulphur Springs, July 10-12. Mr. Joe W. Savage, Public Library Bldg., Charleston, Executive Secretary.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1929 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

American J. Digestive Diseases, Huntington, Ind.

G: 73-160 (April) 1939

- Characteristics of Certain Experimentally Produced Anomalies of the Gastric Secretory Curve. C. M. Wilhelmj, R. W. Finegan and D. E. Bacon, Omaha.—p. 73.
- Histologic Study of Hypervitaminosis D.: Relative Toxicity of Vitamin D of Irradiated Ergosterol and Tuna Liver Oil. R. S. Harris, B. D. Ross and J. W. M. Bunker, Cambridge, Mass.—p. 81.
- Hepatic Glycogen in Obstructive Jaundice: I. Comparative Effect of Oral and Intravenous Dextrose Administration. B. M. Banks and J. B. Sears, Boston.—p. 83.
- Management of Peptic Ulcer Hemorrhage. D. C. Browne and G. McHardy, New Orleans.—p. 87.
- Bleeding Peptic Ulcer (Report of Eighty Cases). G. C. Turnbull and J. H. Sagi, Evanston, Ill.—p. 92.
- *Pectin and Nickel Pectinate in Acute and Chronic Bacillary Dysentery. L. H. Block, A. Tarnowski and B. H. Green, Chicago.—p. 96.
- Influence of Ingestion of Nickel Pectinate on Growth of Young Rats. L. Arnold, Chicago.—p. 103.
- Bactericidal Action of Pectin and Metal Pectinates. L. Arnold, Chicago.—p. 104.
- Para-Esophageal Hiatus Hernia and Related Conditions. T. A. Johnson, Philadelphia.—p. 106.
- Use of Food in Treatment of Bleeding Peptic Ulcer (Meulengracht Diet). W. D. Mayer and J. J. Lightbody, Detroit.—p. 108.
- Clinical Experience with Crystalline Insulin. A. Levitt and S. J. Jaskiewicz, Buffalo.—p. 110.
- Chronic Granuloma of Small Intestine. D. S. Likely and J. R. Lisa, New York.—p. 113.
- Effect of Apples and Cranberries on Calcium Retention. A. Mindell, W. B. Esselen Jr. and C. R. Fellers, Amherst, Mass.—p. 116.
- Urinary Elimination of Free Phenolphthalein No Test for Gastrointestinal Ulceration. F. Steigmann and J. M. Dyniewicz, Chicago.—p. 120.

Pectin and Nickel Pectinate for Dysentery.—Block and his associates compared the effects of pure pectin and nickel pectinate in bacillary dysentery. They found pure pectin to be ineffective; nickel pectinate to possess detoxifying bactericidal and antihemorrhagic properties and to be effective in the treatment of bacillary dysentery. The results in the majority of ninety-five cases treated with nickel pectinate were excellent. Definite improvement was observed in the appearance and general condition of every patient, and this was accompanied by the disappearance of all acute symptoms, tenesmus and bloody diarrhea and an increase in weight.

American Journal of Physiology, Baltimore

126: 1-214 (May) 1939. Partial Index

- Salt Taste Threshold of Humans. C. P. Richter and Alice MacLean, Baltimore.—p. 1.

- Inhibition of Gastric Motility Associated with Presence of Products of Protein Hydrolysis in Upper Small Intestine. J. E. Thomas and J. O. Crider, Philadelphia.—p. 28.
- Diffusion of Calcium, Magnesium and Phosphorus into the Peritoneum: Effect of Intravenously Injected Calcium Salts and of Parathyroid Hormone. A. Cantarow and V. G. Haury, Philadelphia.—p. 66.
- *Effect of Carmine on Gastrointestinal Motility of Children. Icie G. Macy, L. Reynolds and Helen J. Souders, Detroit.—p. 75.
- Economy of Effort Index for Hearts of Normal and Hypertensive Subjects. G. W. Wright, W. R. Hilaran and C. J. Wiggers, Cleveland.—p. 89.
- Effect of Phospholipid Ingestion on Gas Exchange in Man. R. Reiser, Durham, N. C.—p. 109.
- Studies on Secretion of Bile. C. R. Schmidt, J. M. Beazell, A. L. Berman, A. C. Ivy and A. J. Atkinson, Chicago.—p. 120.
- Kinetics of Cholinesterase in Blood and Spinal Fluid. M. B. Bender, New York.—p. 180.

Carmine and Gastrointestinal Motility.—According to Macy and her co-workers, x-ray study of the effect of from 0.2 to 0.3 Gm. of carmine on the gastrointestinal motility of seven average healthy children from 7 to 11 years of age indi-

cated that the carmine had little effect on the total retention time of a test meal (2 ounces of barium, 4 ounces of water). However, definite changes in the motility of the sections of the gastrointestinal tract were produced by the carmine. The average emptying time of the stomach was 257 minutes with the test meal alone; with the test meal preceded by the carmine the average was 177 minutes. The percentage decrease in emptying time of the stomach with the carmine meal ranged from 21 to 51, with an average of 31. The roentgenograms indicated that, after leaving the stomach, the test meal without carmine tended to increase the speed of its passage until, about four or five hours after ingestion, the progress made by the two meals was approximately equal. Complete records of the time of each defecation during the twenty-six days within which four test meals were followed roentgenographically did not show variations which could be attributed to the carmine.

- Compulsory versus Voluntary Methods of Venereal Disease Control in Scandinavia, Holland and Great Britain. A. W. Towne, Syracuse, N. Y.—p. 348.

Premarital Examinations.—Brunet and Salberg discuss the observations in 913 women patients receiving a premarital physical examination and necessary laboratory tests. The average age for the group of 913 women was 23 years, with a range from 16 to 57 years. The details of the sexual life, pregnancies and abortions of the group are discussed. Of the 913 women, six white and three Negro women had received treatment for gonorrhea. One white patient had been treated for syphilis. The number of applicants for marriage certificates in Illinois who have given positive blood Wassermann and Kahn tests amounts to 2 per cent. The state health department reported 896 positive reactions out of 47,781 examined up to July 1938, which is a rate of 1.9 per cent. Of the 913 women, 905 of whom were white, seven white patients were found to have gonorrhea and seven syphilis. None of these patients had both infections. Of the eight Negroes, one was found to have latent syphilis and two were suffering from both gonorrhea and syphilis. The rate for the entire group is 2 per cent and for the white women alone 1.5 per cent. The authors state that this law prohibiting the marriage of individuals with positive serologic tests is wholly unjust, and in persons with congenital syphilis it may be a violation of their constitutional rights. They seriously question the authority and legality of such a statute to prevent the marriage of individuals on this basis. The law should be amended so that the examining physician will be the final authority as to the physical fitness of persons desiring to marry.

Mapharsen for Syphilis Complicating Pregnancy.—Castallo and his co-workers treated 116 syphilitic pregnant women with mapharsen and bismuth. Twenty-six were primigravidas, none of whom had received previous treatment. Among the multigravidas, twenty-two had received treatment in earlier pregnancies. Treatment consisted of weekly intravenous injections of 40 mg. of mapharsen and intramuscular injections of bismuth salicylate in oil. A total of 849 injections containing 31,940 mg. of mapharsen were given. There were 106 live births for the entire group. Among seventy-six patients who received six or more treatments there were seventy-two live births. There were only forty-one live births among forty-nine patients who started treatment before the sixth lunar month. There were ten fetal deaths, seven being stillbirths and three

miscarriages. These mothers received from one to ten treatments, the average being five. Fifty of the 106 babies born alive have been followed in the pediatric clinic. Five proved to be Wassermann positive. Nausea and vomiting following the first few injections occurred in almost every woman. Persistent gastrointestinal reactions were frequent, occurring in sixty-six of the group. In six instances these were so severe as to necessitate withdrawal of the drug. Relative or actual loss in weight was common. The results are compared with those obtained in similar groups of patients who had been treated with neoarsphenamine, acetylarsan and quinine iodobismuthate, and the authors believe that neoarsphenamine is the drug of choice for the treatment of syphilis complicating pregnancy.

*Incidence of Tuberculous Infection in Student Nurses. Ruth E. Boynton, Minneapolis.—p. 671.
Spontaneously Acquired Tuberculosis in Rhesus Monkeys. K. C. Smithburn, New York.—p. 675.

Postmortem Incidence of Tuberculous Tracheobronchitis.—During a period of three years Flance and Wheeler examined the trachea and bronchus in 285 cases of pulmonary tuberculosis that came to necropsy. Nine cases of gross tuberculous tracheo-bronchitis, proved by microscopic study, were found, a total incidence of 3.1 per cent. Of these nine cases, seven were tracheal ulcers, one was a case of ulceration associated with stenosis of the left main bronchus, and the ninth case was one in which no ulcerations were seen but only submucosal tubercles. On checking through the clinical histories of these cases the authors found no symptoms of marked wheezing, dyspnea, cyanosis or sputum changes other than those attributable to a moribund state.

Incidence of Tuberculosis in Nurses.—Boynton compared the incidence of tuberculous infection as evidenced by a change from a negative to a positive tuberculin reaction in students in the College of Education, student nurses in a general hospital service and student nurses in a special tuberculosis service. Of 228 students who entered the College of Education in the years 1930 and 1931, 26.8 per cent had a positive tuberculin reaction. Of the 167 of this group who were tuberculin negative in the freshman year, 149 were retested four years later. Only one of the 149 had become tuberculin positive during this time. Of the 239 student nurses entering the University School of Nursing during the years 1933 to 1937, 29.9 per cent showed a positive tuberculin reaction. Forty-one of these nurses became tuberculin positive when retested early in the second year of training. Undoubtedly many patients with undiagnosed active tuberculosis are admitted to general hospitals for surgery or emergency care and are a grave source of infection to the medical and nursing personnel. Tuberculin tests were given to 367 student nurses one week before beginning a special tuberculosis service. Of these 170, or 46.3 per cent, were tuberculin negative. One month after completing this service, 158 of the

students who were negative to tuberculin at the time they started the service were retested. Thirty-five of the 158, or 22.2 per cent, had become infected with tuberculosis as shown by a change from a negative to a positive tuberculin reaction. It is seen that the tuberculosis-infection rate for student nurses in a general hospital service is 100 times as great and for student nurses in a tuberculous service 500 times as great as that for students in the College of Education.

Suppurative Pericarditis.—According to Bigger, the records of the Medical College of Virginia Hospitals show that the diagnosis of acute pericarditis has been made in fifty cases during the last eight years. Twenty-six were made by clinicians and twenty-four were first made by pathologists, showing that 50 per cent of the cases are not diagnosed clinically. One of the chief factors in the failure to diagnose acute pericarditis is the absence of significant symptoms. Suppurative pericarditis, which is almost always secondary to infection elsewhere, is likely to be obscured by the associated or antecedent disease. This is especially true when the primary infection is within the thorax. Therefore a correct diagnosis will not be made often unless physicians make repeated examinations of the cardiac area in septic cases, especially those with intrathoracic or subphrenic infections, and in osteomyelitis with septicemia. The physical signs are usually more characteristic than are the symptoms. It is probable that a friction rub occurs at some time in all such cases, and it not infrequently persists even in the presence of a large accumulation of fluid; but in other instances it is transient. If a friction rub is not heard and there is no appreciable increase in the amount of intrapericardial fluid, the diagnosis cannot be made, but, fortunately, in those cases in which the diagnosis is of the greatest importance there is a rapid increase in the amount of fluid, which produces the signs of cardiac tamponade. In such cases physical examination will show an increase in the area of pericardial dullness and roentgenograms will demonstrate an enlarged pericardial shadow, while fluoroscopic examination will show an apparent immobility of this shadow. These signs are strong evidence of the presence of a pericardial effusion, but that an effusion is purulent can be proved only by pericardicentesis or pericardiostomy. However, if the diagnosis seems clear it is probably better to proceed with the pericardiostomy without preliminary puncture, as pericardicentesis is not without danger.

Mesenteric Lymphadenitis.—Of the eight patients with mesenteric lymphadenitis whom Wise questioned, six gave histories of recent or fairly recent infections of the upper part of the respiratory tract; two had no such record. As most

of the patients were children, such a history may be a coincidence rather than cause and effect. Four patients have had subsequent respiratory infections without abdominal symptoms. Two had histories of symptoms recurring for a year or more. This would seem to cast doubt on the poliomyelitis hypothesis, as that disease does its damage promptly, does not recur and confers immunity. In none of this series did paralysis develop. One patient suffered from unusually severe allergies and had a chronic *Streptococcus viridans* infection of the throat. Since appendectomy he has had no more abdominal symptoms, yet microscopic examination showed the appendix to have an obliterated lumen. An unusually large lymph node the color of liver removed from the meso-appendix was sterile and no filtrable viruses could be demonstrated. Though the seasonal incidence (fall) has not been corroborated by other observers, the author states that in his series it was paralleled by other admissions to Mercy Hospital with one exception. This brings up the question of food and atmospheric or other seasonal factors. Appendectomies were performed on the eight patients and seven have been entirely relieved. One patient cannot be traced. A ninth patient, who was not operated on, continues to have abdominal symptoms. The patient with the various allergies remains ill of the *Streptococcus viridans* throat infection and allergic manifestations but no longer complains of abdominal symptoms. The author wonders why the removal of rather innocent looking appendices in these cases should produce such a large percentage of symptomatic cures. Two of the seven patients accounted for have been followed for a few months and five for more than a year.

Fatal Pulmonary Embolism.—In a review of 1,781 consecutive unselected necropsies performed on adults between Jan. 1, 1926, and Oct. 31, 1937, Russum and Kemp found twenty-four cases of fatal pulmonary embolism (five were post-traumatic, five followed medical treatment, thirteen were

postoperative and one was post partum). The material came from general hospitals and from the coroner's service. A study of the material and a survey of the literature indicate to them that ages between 40 and 60, the female sex, operations on the abdomen and the pelvis, heart disease and obesity with normal or subnormal blood pressure are factors favorable to embolism. Eight of the twenty-four patients had nonfatal embolism preceding the fatal attack by from three hours to thirty days. Such nonfatal embolism occurred on an average of five days after operation or trauma. Shock should be the criterion for diagnosing embolism; the most common symptoms are perspiration, imperceptible pulse, weakness and pain in the chest. The average postoperative fatal embolism occurred on the sixteenth day, while death from post-traumatic embolism occurred on the forty-first day. Of the fifteen patients who died suddenly necropsy disclosed occlusion of the main pulmonary artery and its main branches in four and occlusion of both large branches in five. The remaining nine patients lived from eight minutes to twenty-four hours. If conditions had been favorable, emergency embolectomy could have been performed on five.

Azochloramid for Chronic Indolent Wounds.—Newell used azochloramid in triacetin (1:500) in the treatment of eight large and necrotic wounds. The wounds were indolent in character and most of them complicated by other factors, such as diabetes or vascular disease. Six of the eight presented localized infection. A satisfactory response was obtained in five of the six cases. The character of the granulation tissue changed after a few days from sluggish, gray granulations into a rapidly growing bed of red granulation tissue of healthy appearance. In the sixth case there were signs of irritation on the second day, and the solution was discontinued. In the other two cases the infections were not sufficiently localized and hot saline compresses seemed of greater value. Sterile sponges soaked in this solution, changed two or four times a day, exert a continuous antiseptic action and require a minimum of attention. Other types of therapy previously tried in these cases offered little or no benefit.

Pelvic Rectal Abscess and Retroperitoneal Cellulitis.—Thompson and Dunphy point out that the fatal termination of a case of ischio-rectal or perirectal abscess is occasionally caused by a complication sometimes called *pelvic abscess*, which is an extension of the infection above the pelvic diaphragm in the retroperitoneal tissues. At times this infection is not localized as an abscess but as a rapidly spreading cellulitis with extensive invasion of the retroperitoneal spaces. Two cases with this type of retroperitoneal infection seen by the authors and one obtained from the records of the Peter Bent Brigham Hospital illustrate the course and treatment of this disorder. Ordinarily the pelvic diaphragm offers an effective barrier to the upward extension of infection about the anus. However, when the lesion of the intestine is above the pelvic diaphragm or when a fulminating infection with gas-producing organisms extends upward by way of the lymphatics of the middle hemorrhoidal vessels, it is quite possible that an extensive infection of the retroperitoneal spaces of the pelvis and abdomen will occur. In order to prevent this sort of complication, early incision and drainage of ischio-rectal abscesses without waiting for localization is advised. Only one patient, in whom early perineal and abdominal drainage was carried out, recovered. This type of spreading retroperitoneal infection causes greater fever and lesser signs of spasm or tenderness of the abdomen than does peritonitis of an equivalent severity. The condition is probably more common than discussion in the textbooks and literature would indicate.

Sulfanilamide and Serum in Pneumonia.—From November 1937 to May 1938 Finland and Brown studied the immune reactions of a group of patients with pneumococcus type III pneumonia before and during treatment with sulfanilamide and type-specific antipneumococcus rabbit serums used separately or in combination. They also observed the effect of these substances in vitro on the bactericidal action of the blood of the patients taken before treatment. Their conclusions are that sulfanilamide in concentrations of 7 mg. or more per hundred cubic centimeters of blood inhibits the growth of large numbers of type III pneumococci in the blood of individuals with or without pneumonia due to this organism when such bloods lack pneumococcal activity. The drug probably does not influence phagocytosis in these bloods. It usually exerts no bactericidal effect in a concentration of 10 mg. per hundred cubic centimeters but may do so in greater concentrations. Patients with pneumococcus type III pneumonia, whose blood is bactericidal for pneumococci of the homologous type during the acute stage of the disease and before treatment, usually acquire homologous type-specific agglutinins, mouse protection and phagocytosis after treatment with either sulfanilamide or serum or both. Blood invasion does not occur after treatment in such cases and if death occurs it is usually due to superinfections or to other conditions not directly related to infection with type III pneumococci. In an occasional patient the pneumonia extends in spite of the presence of circulating antibodies and in spite of the absence of bacteremia throughout the disease. Therapeutic antipneumococcus rabbit serums induce pneumococcal activity in the blood of patients ill with pneumonia due to this type. Antiserum and sulfanilamide used together have a greater bacteriostatic and bactericidal effect than the same amounts of either the serum or the sulfanilamide used separately. The bactericidal promoting property of the antiserum is usually accompanied by demonstrable phagocytosis. In patients whose blood lacks bactericidal properties, treatment with sulfanilamide probably renders the blood bacteriostatic until heat stable specific antibodies develop or until a balance of such antibodies is passively introduced, when the infection is usually overcome. With antisera in proper amounts, the infection may be overcome without the additional use of sulfanilamide, especially in patients who are not heavily infected. Following treatment with sulfanilamide alone, occasional patients with type III pneumo-

coccus pneumonia recover without developing demonstrable homologous type-specific antibodies. This may occur even if the pneumococcus is recovered from the blood stream.

Renal Circulation During Spinal Anesthesia.—Smith and his collaborators discuss the effects of high spinal anesthesia on the circulation. Twenty-one normal subjects were studied. It is concluded that the renal arterioles are distinctly autonomous in the sense that under basal conditions the renal vascular tone is not affected by anesthetic denervation. The observations further suggest that the arteriolar bed generally (apart from the skin) possesses considerably more autonomy than is usually attributed to it—sufficient in fact, in the normal supine person at rest, to maintain an essentially normal arterial pressure. The authors found no evidence of significant arteriolar dilatation during high spinal anesthesia, such reduction in blood pressure as occurs being attributable, they believe, to diminished circulating blood volume in consequence of the dilatation of the capillaries, venules and veins. Anesthesia to levels considerably above those at which the efferent sympathetic paths to the kidneys emerge from the cord does not produce renal hyperemia, nor does it have any other consistent effect on the renal circulation. The tone of the renal arterioles is normally maintained by autonomous, intrinsic activity of the peripheral vascular apparatus and is not dependent on tonic activity of the central nervous system. It is inferred that (like the renal arterioles) the arterioles of the other splanchnic viscera and probably the skeletal muscles possess sufficient autonomy to maintain a normal blood pressure after denervation, provided the method of denervation is not such as to precipitate severe circulatory disturbance. It is a corollary of this conclusion that there is normally negligible tonic activity in the sympathetic vasomotor paths. The peripheral vasomotor system in man under spinal anesthesia is highly resistant to hypercapnia and anoxemia, which precipitate circulatory collapse in the anesthetized sympathectomized dog and cat and in the anesthetized cervical dog by dilating some as yet undetermined portion of the vascular bed. The absence of important tonic activity in the sympathetic vasomotor paths to the arterioles generally, and to the kidneys especially, refers only to normal man in the resting, basal condition and in the supine position. It remains to be determined to what extent sympathetic activity may be evoked by traumatic excitation, by the assumption of the upright posture, by excitement, in hypertensive disease and the like.

 *Radioactive Iron and Its Metabolism in Anemia: Its Absorption, Transportation and Utilization. P. F. Hahn, W. F. Bale, E. O. Lawrence and G. H. Whipple, Rochester, N. Y.—p. 739.

Radioactive Iron and Its Metabolism in Anemia.—Hahn and his associates determined the absorption, storage and utilization of iron in anemic dogs, using iron containing the radioactive isotope. They found that when there is a distinct need for the element (as in anemia) a fair quantity will pass from the gastrointestinal tract into the blood stream. When the body reserves of iron are ample, little of the iron is assimilated. That the mechanism for this reaction may be dependent on a concentration gradient existing between the gastrointestinal contents and the mesenteric blood is doubtful, since the iron in the blood (in a form other than hemoglobin) is present in

minute amount in any case as compared with the amount in the gastrointestinal tract itself. The curve of iron absorption by the anemic dog indicates that the peak absorption (from four to eight hours after feeding) takes place when the food materials are largely in the small intestine. At the end of from eighteen to twenty-four hours the radioactive iron is practically all in the colon and no significant absorption of iron is demonstrable. It would seem that the colon is not concerned with iron absorption. It is shown that the plasma is the site of transportation of iron from the intestinal tract to the point or points at which it is further utilized. Like many other materials the absorption, as indicated by plasma iron changes, increases shortly after feeding to a peak and drops off quite rapidly. Absorption from a given dose of iron probably is complete in the dog at the end of eighteen hours. If an anemic dog is fed neutral iron, the earliest time at which it appears in the blood stream is from about three to five days, as shown by the erythrocyte surge into the circulation. However, in some of the dogs in their present experiments the authors observed that the radioactive iron found its way into the erythrocytes much sooner; in fact, appreciable amounts are demonstrable in a few hours. The authors point out that discrepancies in iron balance studies in human subjects have sometimes been explained as due possibly to adsorption of iron to the mucosa of the gastrointestinal tract leading to a false impression of positive balance. In two of their dogs in which viviperfusion followed the last feeding of radioactive iron by twenty-three hours, practically all of the iron had been swept through the upper part of the gastrointestinal tract and had either been eliminated or was in the colon. The stomach and small intestine of one of these dogs contained only 0.46 per cent of the total isotope fed, whereas the colon contained 52 per cent. The upper part of the gastrointestinal tract of the other dog contained 0.24 per cent of the amount of radioactive iron fed, while the colon and feces contained 82 per cent. The material fed in each case consisted of iron in the ferric form, which would be expected to show adsorption (if present) to a greater extent than ferrous iron compounds.

Comparison of Tuberculin Tests.—Canuteson reports the results obtained in three years of tuberculin testing covering a total of 4,108 students. An average of 16.94 per cent of positive reactors was isolated with a single intermediate dose and 40.1 per cent with the regular two dose test. The incidence of the adult type of tuberculosis was 0.512 per cent with the intermediate dose and 0.609 per cent by the regular two dose method. There were no four-plus reactions with the small intermediate dose of 0.0002 mg. The incidence of four-plus reactions with the large intermediate dose of 0.0005 mg. was 1.004 per cent and with the routine two dose test it was 0.355 per cent. Retesting the negative reactors to the large intermediate dose with the regular second dose increased the positive reactors in a group of 735 students from 15.37 per cent to 35.51 per cent and the incidence of secondary tuberculosis from 0.54 per cent to 0.68 per cent, representing one additional inactive

case. The incidence of secondary tuberculosis determined by use of the smaller intermediate dose of 0.0002 mg. was 0.508 per cent and by the larger intermediate dose of 0.0005 mg. was 0.515 per cent.

Neurectomy for Vesical Atony.—Huggins and his associates discuss the results of section of the principal nerves to the urinary vesical sphincters in eighteen cases of neurogenic atony of the bladder. The diagnosis of vesical atony was made by cystometric study and by clinical, neurologic and cystoscopic examination. The results of the treatment should not be judged until the patient is ambulatory. Apparently marked improvement occurred in four of eleven cases of neurogenic paresis of the bladder, treated by presacral neurectomy, while in four cases the improvement was slight and in three none was demonstrable. In three children with urinary retention with vesical atony but without signs of either somatic nervous disease or urinary obstruction the retention was lessened by presacral neurectomy. Many clinical features in these cases suggested that the condition may have been the urinary tract analogue to congenital megacolon described by Hirschsprung. Good results from presacral neurectomy were obtained in localized lesions of the cauda equina or sacral cord when the lumbar nerves were intact, producing a large amount of residual urine in the bladder, with or without paradoxical incontinence. Sympathectomy was not beneficial when the disease had produced appreciable injury to the pelvic nerve or sphincter with true incontinence and in tabes dorsalis. Following sympathectomy in appropriate cases, emptying of the bladder is produced by straining. The improvement may persist for at least six years after operation. In six cases unilateral pudendal neurectomy with or without presacral neurectomy was followed by a moderate improvement in five

cases. In two cases incontinence of urine was present before operation and this persisted following neurectomy, although less in amount. There was no incontinence in four. There has been no fecal incontinence. A weakened anal sphincter on the ipsilateral side is observed after operation. In one case bilateral pudendal neurectomy with transurethral resection of a small amount of prostatic tissue was followed by nocturnal incontinence, but no diurnal leakage, and a large decrease in the amount of residual urine in the bladder.

Hyperparathyroidism and the Urinary Tract.—Chute points out that at the Massachusetts General Hospital during a period of eight years there was a total of thirty-six cases of hyperparathyroidism in 62,000 hospital admissions. The diagnosis was confirmed at operation and by pathologic examination. Women were affected more than twice as often as men. The average age in the series was 43, the oldest patient being a woman of 62 and the youngest a girl of 12. General symptoms found in hyperparathyroidism are weakness, ease of fatigability and constipation. These are probably due to hypercalcemia, which reduces the tone of nerves and muscles. Polydipsia and polyuria were usually present and were attributed to the increased excretion of calcium and phosphorus in the urine—analogueous to the polydipsia, polyuria and glycosuria of diabetes mellitus. The polyuria is sometimes so marked as to suggest diabetes insipidus. In addition to these general symptoms, the predominating complaints in more than half of the thirty-six cases were of urinary tract origin. They are due to calculi and consequent renal damage and may take the form of renal or ureteral colic, bladder irritation, blood and pus in the urine and the like. Sometimes, especially when bilateral generalized calcifications exist throughout the renal parenchyma, the presenting signs and symptoms may be those of kidney failure and uremia. Other somewhat less common special symptoms arise from the decalcification of the skeleton and may take the form of flat feet, weakness of the legs, aches and pains in the bones and joints simulating arthritis or neuritis and loss of weight. Urinary calculi were present in thirty of the thirty-six cases. The calculi were bilateral in 53 per cent and multiple in 73 per cent. They naturally tend to recur, after removal or passage, until the underlying hyperparathyroidism has been remedied. All of the calculi show a lot of calcium and phosphorus on analysis, and in addition most of them show some oxalate and a few show carbonate. The diagnosis rests fundamentally on the demonstration of an elevated fasting serum calcium. The normal value for this is about 10 mg. per hundred cubic centimeters of blood. The average in the thirty-six cases was 13.76 mg. It is well to check all serum calcium estimations by the Sulkowitch test and see whether the two agree. Since hyperparathyroidism is due to excess production by the parathyroids of their hormone, the only satisfactory results, just as in the case of the thyroid, have been obtained by surgical resection of the hyperfunctioning tissue. There was no operative mortality in the author's thirty-six cases. Four patients died later of renal insufficiency due to multiple calculi and one patient died later of coronary thrombosis. While the follow-up period is no longer than six years, so far all have remained clinically free from hyperparathyroidism with essentially normal calcium values. The formation of calculi has ceased and no new calculi have formed in any case to the best of the author's knowledge.

Syphilis and Pulmonary Tuberculosis.—Guilbert and his associates report the results of the treatment of syphilis in 118 patients also having pulmonary tuberculosis. Of the sixty-six white patients 65.1 per cent were improved, and of the fifty-two Negro patients 46.2 per cent were improved. From a study of the results the authors believe that the treatment of syphilis in patients with coexisting pulmonary tuberculosis who show a definite tendency toward favorable progress does no harm and is of real benefit. Patients whose prognosis for the tuberculosis is bad probably will receive no benefit from the antisyphilitic treatment. Antisyphilitic treatment in the doses given by the authors showed no predisposition to pulmonary hemorrhage. Patients receiving the maximal dose of neoarsphenamine (0.9 Gm.) seemed to tolerate it as well as those receiving the smaller doses. The type of syphilis in 90 per cent of the series was latent.

Roentgen Treatment of Infections.—Kelly and Dowell used a mobile x-ray apparatus in the treatment of eighty-one patients with peritonitis, cellulitis, surgical mumps, gas gangrene and other infections. Of these patients seventy-three are living, giving a mortality of 9.87 per cent. The authors believe that the treatment has been of definite benefit and recommend that it be used by others. If the treatments are given under the direction of an experienced radiologist there are no absolute contraindications. Repeated small doses of from 50 to 70 roentgens morning and evening for from three to five days during the height of the infection are recommended. The correct technical factors must be prescribed by the radiologist so that the total dosage given is under the minimum which might damage the skin. Some filter should be used at all times. The

kilovoltage should be sufficient to penetrate the involved area thoroughly: from 90 to 135 kilovolts. Sufficient ports should be used so that all involved tissues and adjacent suspected areas are covered. The distance is 15 inches (40 cm.). The reason for treating twice a day, which the authors insist on, is based on the observation that the results in the treatment of infections were better when the space factor or time between treatments approximately coincided with the rate of growth (on culture mediums or by clinical estimation) of the causative organism.

Sulfanilamide in Acute Streptococcal Mastoiditis.—

According to Noble, the use of sulfanilamide was successful in all but one of twenty-four cases of acute mastoiditis. The infection in all but one was due to *Streptococcus haemolyticus*. In the exception it was due to *Streptococcus viridans*. There was a history of previous attacks of otitis media in ten of the cases. A history of measles preceding the otitis media was given by five patients, with scarlet fever as a predisposing cause by one. A bilateral mastoidectomy was necessary in only one case. Three of the twenty-four patients had acute recurrent trouble from three to six months after the simple mastoidectomy, which necessitated myringotomy and incision of the mastoid wound. The average number of days in the hospital following the simple mastoidectomy for the entire group was eleven and one-sixteenth days. There was complete recovery of all but one patient, who died of acute purulent meningitis (*Streptococcus viridans*) and diabetes mellitus.

Chronic Brucellosis.—During a period of three years Calder examined nearly 1,300 chronically ill subjects for brucellosis by the Foshay antiserum cutaneous test and opsonocytaphagic and agglutination reactions. In more than half of the cases laboratory examinations have been adequate to exclude numerous diagnostic possibilities. Tuberculosis, which might account for the clinical picture, was excluded in most instances by x-ray examination. That each of the three reactions is a specific result of *Brucella* invasion is shown by the fact that: 1. Each of the tests is positive in a significantly higher percentage of patients with symptoms of chronic brucellosis than in those who are normal or ill with other infectious diseases or with afebrile illness of known etiology. 2. The mass symptomatology of 550 consecutive subjects showing a positive cutaneous test is strikingly similar to that of patients in whom the diagnosis of brucellosis was established by culture or agglutinations. 3. The blood picture in these cases, characterized by active lymphocytosis, hyperchromia and macrocytosis, is definitely abnormal and is duplicated in its entirety by few if any other infectious processes. 4. Finally, when patients with positive tests are subjected to specific treatment approximately 80 per cent of them are cured symptomatically; and this subjective response is almost invariably accompanied by the development of a high titer of opsonins specific for *Brucella*. The present analysis indicates that if any two of these tests are positive the

chances are about seventy to one that the clinical symptoms will be found compatible with a diagnosis of brucellosis. It would appear good practice, therefore, not to place sole reliance on any one of the tests but to perform all three and to interpret the results in the light of the clinical picture. If other possibilities are excluded, selection of cases by these criteria and treatment with oxidized *Brucella abortus* antigen (Foshay) will result in an apparent arrest of the infection in a gratifying number of cases.

Estrogen Therapy and Photosensitivity.—In studying a group of six female patients affected with photogenic dermatitis Lancaster eliminated any of the known photosensitizing drugs by careful investigation. There was a definite history of menstrual disturbance in the five adults, most of whom had a history of menstrual disturbance preceding the dermatitis, but in two the dermatitis preceded the menstrual disturbance two and three years respectively. Most of the married women studied gave a history of sterility. Many gave a clinical history of symptoms long recognized as being associated with estrogenic deficiency and these symptoms were benefited by its administration. Improvement in the dermatitis and menstrual disturbance appear to parallel each other. In the younger adults in whom the menstrual disturbance preceded lowered tolerance to sunlight, correction of the menstrual disturbance has been accompanied by a permanent restoration of tolerance to sunlight. But in those in which the dermatitis preceded the menstrual disturbance it has been necessary to give injections at variable intervals, depending on the appearance of the dermatitis. Even though endocrine therapy is mostly speculative the author is of the opinion that there is a definite estrogenic deficiency in female patients suffering with photogenic dermatitis. He is thoroughly convinced that estrogen has a definite place in the management of sunlight eruptions in women and that, judiciously used, it will aid in the solution and management of the allergic patient.

Thrombophlebitis and Venous Occlusion.—Paine and Levitt report four cases of thrombophlebitis of the lower extremities of recent origin and seven cases with a duration of two months or longer treated with intermittent venous occlusion at the University of Minnesota Hospitals. The immediate results have been so striking that, despite the lack of adequate controls and follow-up study, they are reported. After establishing a diagnosis of thrombophlebitis on the basis of history and physical examination, the patients were treated continuously for three or four hours a day five or six days a week with intermittent venous occlusion. During each period of treatment, patients were kept recumbent with the lower extremities slightly elevated. Venous occlusion was produced by wrapping a rubber

bag 6 inches wide and 24 inches long round the mid thigh and holding it in place with a loosely applied elastic bandage. This bag was then inflated with air to from 70 to 80 mm. of mercury for two minutes. This period of inflation was followed by a period of deflation of equal length during which a slight negative pressure was maintained within the rubber bag. The pressure and time relationships probably fall within the optimal range for the production of reactive hyperemia. Three of the patients were hospitalized and in bed and the other eight were ambulatory. The pain, discomfort and tenderness present in the affected extremity were relieved in each case. In some instances this occurred after only a few hours of treatment, but in certain cases twenty or more hours was required to accomplish the same result. The edema in certain cases was unquestionably decreased a great deal, in others improved somewhat and in still others unaffected. If improvement did occur, a certain order of events occurred. Induration, if present, decreased first. The skin and subcutaneous tissues became softer and more pliable. The subjective stiffness of the joints improved as the induration decreased in six of the seven cases in which it was present. In certain cases improvement in the edema progressed no further than this, no actual decrease in the size of the leg being demonstrable.

Sulfanilamide in Surgery of Colon and Rectum.—In order to reduce the incidence of postoperative peritonitis, Garlock and Seley tried using sulfanilamide preoperatively as a prophylactic measure in twenty-one consecutive cases in which operation was performed for diseases of the colon and rectum. There were two deaths. One death followed an obstructive resection for carcinoma of the splenic flexure. This patient experienced an uneventful convalescence until the seventh day, when he suddenly went into collapse and died within five minutes. Clinically, either a pulmonary embolism or a coronary artery occlusion was suggested. There was no postmortem examination. The second patient had an abdominoperineal resection for carcinoma of the rectum in one stage. His postoperative course was uneventful until the fifth day, when pulmonary edema developed quite suddenly. The clinical picture suggested coronary artery disease. Death occurred within six hours and at necropsy a fulminating tracheobronchitis and bronchopneumonia were observed. The peritoneal cavity was perfectly clean, as was also the perineal wound. The colostomy had been functioning properly. The authors discuss the condition of some of the other patients. There was a major wound infection in only one case and this was expected. This patient had an obstructive resection for a perforated carcinoma of the sigmoid with a perisigmoidal abscess, and gross soiling of the wound and adjacent peritoneum occurred during the operative manipulations. Yet, in spite of this, convalescence was remarkably smooth. In another case of obstructive resection of the sigmoid a small stitch abscess developed. In a third case a mild infection of the posterior wound developed following an abdominoperineal operation. In two cases of abdominoperineal resection for carcinoma of the rectum, the rectum was accidentally opened during the perineal part of the operation and gross spilling occurred. Yet no infection developed and convalescence was uninterrupted. In one case of carcinoma of the rectum with considerable fixation to the posterior vaginal wall a two stage Lahey operation was performed, and during the second stage an abscess between the tumor and the vaginal wall was entered and gross soiling of the peritoneum occurred. The operation was continued and a new pelvic peritoneal diaphragm was reconstructed. Except for a temporary mental upset attributed to the spinal anesthesia, convalescence was uneventful. There was no infection of either the anterior or posterior wounds. Cultures of *Bacillus coli* were obtained at the time of the operation. A smooth uncomplicated convalescence ensued in these cases in spite of the fact that there have been no changes in operative technic. The improvement in postoperative morbidity and mortality therefore can be ascribed only to the sulfanilamide. The routine preoperative preparation includes, in addition to a low-residue diet, dextrose, transfusions when necessary, and the administration of 1 Gm. of sulfanilamide by mouth every four hours day and night for three days before operation. After a careful evaluation of the clinical course of this group the authors find that the postoperative period has

been singularly uncomplicated, the morbidity has been unusually slight and peritonitis has been nonexistent. Streptococcus haemolyticus was not recovered postoperatively in any of the cultures. The impression gained is that the results obtained so far warrant a continuation and extension of this study.

Prevention of Maternal and Infant Anemia.—Gottlieb and Streat believe that both the maternal anemia and the anemia of infants, which usually develop in the first year of life in infants of anemic mothers, can be prevented by prophylactic iron therapy. They found ferrous sulfate in combination with vitamin B complex to be most effective without greatly upsetting the gastrointestinal tract. They state that the development of an iron deficiency during pregnancy is easy to understand, since the fetus not only develops its own blood supply during intra-uterine life but actually develops a polycythemia during its prenatal stage, to overcome the normal degree of anoxemia in which it has to live before birth. The iron for the production of hemoglobin must be supplied from the iron storage of the mother. The greater polycythemia in the fetuses of anemic untreated mothers is essential for the maintenance of the oxygenation of the fetal tissues, but the iron storage of these fetuses is apparently deficient and the infant obviously cannot maintain its normal erythrocyte and hemoglobin level during the first year of its most rapid growth and development. Prophylactic iron therapy might prevent many maternal complications and the infant mortality might be reduced.

Treatment of Hypersensitive Carotid Sinus Reflexes.

—Craig and Smith divide the treatment of hyperactive carotid sinus reflexes into three groups: 1. When the symptoms are mild and the attacks occur at infrequent intervals, no treatment is required other than reassurance. 2. When the symptoms are moderately severe and the attacks occur more frequently the patient should be instructed to avoid turning his head quickly, looking upward and stooping suddenly. He should avoid any constriction about the neck. If the spells are quite severe and occur at intervals sufficiently close to interfere with the patient's work or activity, medication is indicated. In the authors' experience drugs have not been particularly satisfactory, but of the many drugs used their results have been best with phenobarbital. 3. When the attacks are severe and a thorough medical course of treatment has been carried out without success, operation is indicated in selected cases. They believe the results that they obtained in thirteen cases justify surgical intervention. One patient's subsequent course could not be followed. In the remaining twelve cases the results were excellent in four, good in one, fairly good in four and poor or failures in three. Since medical treatment is not particularly satisfactory and because of the severity of the disease, in some instances totally disabling the patient, surgery is indicated in certain cases. The operation does not entail a great surgical risk. More cases should be chosen for operation and the results studied further, but the results justify continuation of denervation of the carotid sinus in certain instances.

Functions of Frontal Lobe.—During the last three years Freeman and Watts studied forty-eight patients who have been subjected to prefrontal lobotomy because of certain disabling neurotic and psychotic states. The operation is not a shocking procedure and is relatively painless, so that the authors have been able to carry out a number of observations while the patients were under local anesthesia. The more cooperative patients have undergone fairly comprehensive psychologic tests both before and at intervals after the operation, so that both the immediate and the remote effects of the operation are known. The authors conclude that the frontal lobes are concerned with the projection of the individual-as-a-whole into the future, with the formation of an image of the individual-as-he-is-becoming. The other suggested functions appear to be mechanisms by which this is attained. Many of the symptoms of frontal lobe disease can be explained on the basis that the individual has lost his power of self criticism, is more easily satisfied, is lacking in "social sense" and has had an impairment of his imagination as related to himself. The frontal lobes are not centers of intelligence or of emotion, nor are they directly concerned with the energy drive of the individual. They assemble the available data, synthesize them, plan a course of action with the ideal in mind and, equipped with energy of response and with appropriate affective tone, project the individual into the future, direct him toward his goal—and criticize his shortcomings.

Diagnosis of Schüller-Christian's Disease.—Schüller cites three cases which demonstrate that x-ray examination of the skull in cases of Schüller-Christian's disease can show hyperostotic osseous changes. This symptom, which corresponds to the healing stage of the xanthomatous process in the bone, might be of some value for the diagnosis. The symptoms, as a rule, begin in the skeleton, especially in the skull. Roentgenograms of the skull taken at this time show multiple defects at the vault and at the base of the skull, the orbital walls or the lower jaw. The x-ray examination must include all other bones, especially the pelvis and ribs. A roentgenogram of the lungs may show a diffuse infiltration with miliary nodules. Important anomalies are seen on the skin in many cases; xanthelasma of the eyelids, xanthomatous or seborrheic efflorescences of the skin may be found. Finally, the excellent therapeutic effect of x-rays on the xanthomatous process may help in the diagnosis. Mistakes in the diagnosis of Schüller-Christian's disease are not uncommon, especially in the early stages of the disease. The multiple defects of the skeleton may be mistaken for syphilis, tuberculosis, malignant disease, myeloma, osteitis fibrosa cystica or suppurative osteomyelitis. A wrong diagnosis of xanthomatosis may be made in cases of meningocele spuria traumatica. The large transparencies of the calvarium seen in cases first described as "circumscribed osteoporosis of skull" (corresponding as a rule to incipient Paget's disease) can also be mistaken for xanthomatosis.

Sulfanilamide for Measles.—Between December 1937 and March 1938 Anderson treated sixty-three measles patients with sulfanilamide. During this same period a control group of sixty-two patients received only the usual nursing and medical treatment. The dosage of the drug varied with the age of

the patient. If the patient was less than 5 years of age 0.25 Gm. was administered at intervals of four hours for ten days, followed by 0.25 Gm. three times a day until dismissal; those more than 5 years of age received 0.5 Gm. at the same intervals and for a like period. Apart from the drug the two groups received strictly comparable treatment. All patients were given on admission 4,000 units of diphtheria antitoxin as a prophylactic procedure. All were under the clinical care of one person, so that individual variations in assessment or diagnosis were overcome. Sulfanilamide had little effect in shortening the febrile period after admission to the hospital. There was a slight reduction in the mean duration in the sulfanilamide-treated cases. The results do not suggest that sulfanilamide is of great value in hastening the cure of the major complications of measles. The duration of bronchopneumonia, however, was materially less in patients who received sulfanilamide. In the control group a total of forty-seven complications developed in thirty cases while in the sulfanilamide group twenty-three complications developed in twenty-two cases. The average stay in the hospital of the control group was 26.5 days; in the sulfanilamide group, 25.6 days. Four deaths occurred in the series, one in the control group and three in the sulfanilamide group.

Sulfanilamide Compound for Prevention of Measles Complications.—To half of 329 patients with measles receiving the usual routine treatment such as fresh air, simple drugs and a prophylactic dose of antitoxin Hogarth gave para-benzylamino-benzene sulfonamide in accordance with a fixed scheme of dosage. The total complication rate in the control patients not receiving the sulfanilamide compound was 15.3 per cent, as against 10 per cent among those who received it. Close scrutiny reveals that the results were not equally good with all complications, the incidence of enteritis apparently being quite unaffected by the drug. With regard to other complications, it is inferred that the drug has prophylactic value, as the incidence of bronchopneumonia, acute otitis media and cervical adenitis was less than that of the controls. Therefore there is evidence that the drug is of value in reducing the incidence of complications due wholly or in part to secondary invasion by hemolytic streptococci, the best results being obtained in pure streptococcal complications such as otitis media.

- Staphylococcal Septicemia Treated with Sulfapyridine. Report of Case. H. J. Wade.—p. 756.

Air-Borne Streptococcal Infections.—Bacteriologic and epidemiologic studies of institutional outbreaks of puerperal sepsis and streptococcal infections among children in diphtheria wards have convinced Cruickshank and Godber that air-borne pathogenic bacteria can be an important factor in the spread of infection. Cleansing of the polluted air by free ventilation and the removal of infected dust by damp sweeping and dusting are two simple and probably effective measures for the prevention of air-borne streptococcal infection.

Postoperative Thrombosis and Embolism.—In 406 cases of accidental trauma and surgery Pilcher gave hypodermic injections of ephedrine and atropine as a prophylactic against thrombosis and pulmonary embolism. The injections were given on the fifth, seventh and ninth days after the accident or after the operation. The incidence of thrombosis and embolism was approximately the same as in a control series of 1,265 cases.

Sulfapyridine for Pneumococcal Meningitis.—In their case of pneumococcal meningitis in which McAlpine and Thomas gave sulfapyridine the onset was abrupt. Treatment with the drug was begun on the third day. At the end of thirty-six hours the temperature had fallen to normal in the morning and remained so, apart from a slight evening rise, for the next three

days. The signs of meningitis rapidly cleared up and finally disappeared on the fifth day of treatment after 19 Gm. of the drug had been given. The total amount of sulfapyridine given was 25.5 Gm. over a period of seven days. The highest concentration of the drug in the cerebrospinal fluid was 3 mg. per hundred cubic centimeters.

Illness in Contacts with Confluent Smallpox.—Conybeare reports the more or less simultaneous occurrence of a febrile illness in seven among sixteen contacts of a single fatal case of smallpox. The circumstances suggested that a single pathogenic agent was the cause, encountered during contact with the patient with smallpox. The symptoms were similar in all the persons affected. Symptoms or signs suggesting that a bacterial agent caused the illness were entirely absent. The almost complete absence of localizing signs in the respiratory tract or lungs and the lack of spread to family or other contacts appeared to exclude epidemic influenza. The illness may have been a modified form of smallpox. In two patients there were cutaneous eruptions, and in one the appearance, course and distribution of the rash were consistent with a diagnosis of variola. The apparent incubation period in this patient was seven days, which was also the average apparent incubation period of the whole group. If the illness was a form of smallpox, it is noted that none of the patients infected contacts. The immediate seven contacts were familial and, with one exception, all were successfully vaccinated or revaccinated in time to obtain protection if the illness was smallpox. Therefore failure to infect others is not conclusive evidence against the illness described having been smallpox in a modified form. The experience of the one contact who was not revaccinated during the interval between contact and illness was similar to that of the six who were. This appeared to exclude the possibility that the illness was a form of vaccinia. The last successful revaccination of this person was in 1922, and in him the result of a revaccination after the illness appeared to be important. Accordingly, approximately four months afterward he was revaccinated in one insertion on the left upper arm. The resulting reaction reached a maximum and in four days took the form of a small vesicle, indicating partial retrogression toward susceptibility to smallpox and vaccinia. This does not exclude the possibility that the illness experienced by him in March 1938 was a form of smallpox. Absence of the characteristic eruption might have been associated with failure to develop a complete immunity to vaccinia. It may be concluded from the foregoing that a careful observation of a nonspecific illness occurring within the usual period of incubation in vaccinated or unvaccinated smallpox contacts might reveal factors of considerable importance in the epidemiology of the disease.

*Pneumococcal Peritonitis in Children. S. Williams.—p. 506.
Comparative Study of Some Recent Serologic Tests for Syphilis. E. A. North.—p. 509.

Pneumococcal Peritonitis in Children.—Williams points out that over a period of ten years there were forty-five cases of pneumococcal peritonitis. Fourteen of these were secondary to a primary disease in other sites than the peritoneum. The

remainder were primary or idiopathic. The secondary cases were due to a septicemia from a pulmonary infection in all but one case; in this instance the primary focus was in the petrous temporal bone associated with a pneumococcal meningitis. There is a mortality rate of 80 per cent. Figures show that in secondary pneumococcal peritonitis there is an equal sex distribution. Of the primary cases of pneumococcal peritonitis twenty-nine occurred in girls. The diagnosis was confirmed bacteriologically. The condition should be borne in mind in the differential diagnosis of acute appendicitis, particularly in girls who are extremely ill soon after the first appearance of symptoms. Surgical intervention will usually be required. When the diagnosis is fairly certain without operation, the operation is better delayed and may not be necessary. A diagnostic abdominal paracentesis with examination of the peritoneal fluid for pneumococci may be of value. If immediate treatment is undertaken, the patient is placed in full Fowler's position and given a free fluid diet. If abdominal distention occurs and there is associated vomiting or dehydration, with or without diarrhea, continuous intravenous injection of 5 per cent dextrose in saline solution can be given. Continued abdominal distention and gastric dilatation may be treated by continuous gastric drainage. The use of sulfapyridine in a dose of 15 grains (1 Gm.) per 20 pounds (9 Kg.) of body weight per day may be expected to exert a specific effect on this type of infection, similar to that seen in respiratory pneumococcal infections. Ten thousand units (15 cc.) of Felton's typed serum may be given intravenously and repeated twice a day for five days or until signs of improvement occur. A survey of the clinical reports of primary pneumococcal peritonitis suggests that the usual mode of entry of the pneumococcus is by way of the pelvis. This is also borne out by the sex incidence. If the pus becomes localized to one particular site in the abdomen, operation is indicated.

Virus of Human Influenza.—Yen states that studies of recent years clearly establish the virus etiology of epidemic influenza. It is more than likely that many conditions clinically resembling epidemic influenza have been called epidemic influenza. Thus, in order to avoid such confusion in the future, one may have to limit the definition of epidemic influenza to a disease for which a specific virus of Smith, Andrewes and Laidlaw is responsible. The diagnosis can be established by isolating the virus and transmitting it directly to ferrets, mice, embryonic chick tissue medium and chorio-allantoic membranes or by the virus neutralization test and complement fixation test of serums. Burnet has indicated that the pathogenicity of the virus is alterable on repeated animal passage and cultural environment. Man, ferrets, swine, hedgehogs, white mice, Chinese minks and David's squirrel were found to be susceptible to experimental infection with the virus. The first four respond to the virus infection with acute symptoms of the upper part of the respiratory tract and the induced disease is contagious, while the remaining species show involvement of the lower part of the respiratory tract, and the induced disease is noncontagious. Rats, guinea pigs, rabbits and monkeys respond with inapparent infection or with mild inconsistent symptoms. Active immunity or circulating antibodies can be demonstrated in all the species of animals. The popular belief of frequent repeated attacks of epidemic influenza in the same individual should be reinvestigated. Despite the fact that solid immunity in animals is obtainable after infection with the virus, the exact duration of immunity in man is not yet accurately known. Although specific serum therapy in experimental animals seems encouraging, giving rise to a protective immunity, its possible application in human cases has not been determined.

- *Pyloric Stenosis of Cholecystic Origin. J. Baumel and H. Serre.—p. 241.
Contribution to Study of Induced Hyperglycemia: Capillary and Venous Glycemia. I. Blitstein.—p. 268.

Pyloric Stenosis of Cholecystic Origin.—Under the term pyloric stenosis of cholecystic origin, Baumel and Serre discuss the organic stenoses of the pylorus and of the juxtapyloric region of the duodenum, which are caused by a cholecystic disorder. Among the various factors that may cause them, two are of primary importance: calculus and perivisceritis. Spasm and pyloroduodenitis are well known adjuvant causes. Three factors have an essential part in the pathogenesis: mechanical, infectious and spasmodic. The symptomatology is characterized by the usual signs of pyloric stenosis and by cholecystic symptoms which are helpful for the diagnosis. On the basis of the etiology, several clinical forms can be differentiated. The authors mention (1) the stenosis that is caused by cholecystic compression, (2) the stenosis that is caused by cholecystoduodenal fistula with impacted calculus (type Bouveret), (3) the stenosis caused by pericholecystitis of lithiasic or nonlithiasic origin and (4) the stenosis caused by postoperative perivisceritis. The symptomatology permits the differentiation of many clinical forms. Among the symptomatic varieties which are especially likely to cause diagnostic difficulties it is necessary to remember the forms without vomiting, the forms without cholecystic symptoms in the past and the associated forms. As regards the evolution, two forms can be distinguished: spasmodic stenoses, which cease in response to medical treatment, and the surgical forms, in which the mechanical element predominates. The prognosis is grave if no intervention is undertaken and remains serious in spite of an operation. The diagnosis has to be based chiefly on the anamnesis, the associated symptoms and the absence of signs of ulcer and cancer. The differentiation from cancerous stenoses is often difficult and perhaps can be decided only by an operation. After a trial has been made with medical treatment, surgery is advisable in the form of a gastro-enterostomy or a cholecystic procedure; both of these operations may be advisable, either simultaneously or successively.

*Contribution to Study of Craniocerebral Traumatism: Pathology of Subdural Space. J. Rossier.—p. 625.
Section of Erector Nerves by Gluteal Route. J. Ginestie and A. Delmas.—p. 650.

Subdural Space in Craniocerebral Traumatism.—Rossier reports several clinical histories which illustrate the surgical pathology of the subdural space and also throw light on the pathogenesis of the subdural hematoma. The first observation reveals that after a grave trauma the subdural space may be filled with almost pure blood. This patient presented a veritable subdural hemorrhage. In a less grave lesion the author saw the subdural space filled with cerebrospinal fluid; that is, a subdural hygroma existed (second case). He also observed a typical example of subdural hematoma arising probably from a hemorrhage into the subdural space and from its organization (third observation). Finally he observed a case of endogenic hemorrhagic pachymeningitis (fourth observation). The role of the traumatism is of theoretical as well as of practical interest. In three of the reported cases the role assumed by the trauma cannot be denied and although in the other case it can be doubted, either because it was sustained long ago and was not followed by symptoms immediately or because it was slight, the author believes nevertheless that it is necessary to concede the causal role of traumatism in the development of a subdural hemorrhage in a healthy person. The author has been able to show that a cerebral edema can be provoked by a trauma that was not directly followed by symptoms of commotio cerebri. A mild trauma can cause a hemorrhage into the subdural space without at first producing symptoms. That in a more advanced stage the histologic aspects may be exactly like those of a hemor-

rhagic pachymeningitis is not very surprising. This is only the manifestation of the monotony of reactions of a given tissue to an irritating agent which remains the same: extravasation of blood either into the subdural space (traumatism) or into the thickness of the dura mater itself (pachymeningitis). If it is admitted that the blood which is found in the subdural space after a venous hemorrhage can become absorbed only by the action of the dura mater, it can be understood that at the time when this resorption begins the same conditions exist which mark the onset of a hemorrhagic pachymeningitis: the presence of products of sanguineous disintegration in the dura mater. From that time the two disorders, the traumatic and the dyscrasic, evolve in an identical manner. Thus the two disorders can be differentiated only at the beginning. The traumatic origin adds a subdural phase characterized at first by a free hemorrhage, then by a clot and finally by the organization of the latter. From the moment when the clot is covered by a fibroblastic coating, it can be said that thereafter everything develops as if the abnormally fragile vessels of the dura mater had caused an intradural hemorrhage. Another important aspect is that the process evolves in a closed space; in other words, certain conditions of slow resorption must be preserved. On the other hand, if the accident causes a laceration of the arachnoid, as in one of the described cases, there results a disorder which does not correspond anatomically to the subdural hematoma but which may simulate it clinically. The author summarizes the pathologic aspects of the subdural space by stating that it may contain pure cerebrospinal fluid or a mixture with blood, recent hemorrhages and old hemorrhages having evolved in a manner peculiar to the subdural space. He emphasizes that the term subdural hematoma should be restricted to the posttraumatic disorder and should not be applied to the hemorrhagic pachymeningitis of other origins. In remarks about the treatment of subdural hematoma, he stresses that it should be opened and the drainage should be continued for a sufficient length of time so that the brain will regain its normal volume and the subdural cavity its spatial character.

- *Nervous Complication of Nicolas Favre Disease (Venereal Lymphogranuloma). Lévy-Valensi and S. de Sèze.—p. 593.
Physicochemical and Immunologic Investigations on Blood of Aged Persons. R. Pierret, A. Breton and L. Christians.—p. 594.

Nervous Complications of Venereal Lymphogranuloma.—Lévy-Valensi and de Sèze show that, until now, little attention has been given to the nervous manifestations in the course of venereal lymphogranuloma. They think that these nervous complications are less exceptional than is generally believed. Their attention was called to this problem by the appearance of an acute myelitis in the course of a case of venereal lymphogranuloma in which the examination of the cerebrospinal fluid disclosed the presence of *Proteus vulgaris*. After considering the two possibilities that are suggested by this case, namely that the meningomyelitis was caused by *Proteus vulgaris* or that it was a true nervous complication of venereal lymphogranuloma, they say that in 1931 Nicolas observed in the course of venereal lymphogranuloma persistent headaches, fever and rigidity of the neck, symptoms which are usually attributed to meningeal processes; von Haam and d'Aunoy observed headaches in the acute stage of the disease; sciatic and crural neuralgias were observed by several authors; intense persistent headaches and fever were observed by Prats in fifty-two of 100 cases of venereal lymphogranuloma. Grave nervous symptoms in the form of flaccid paralysis, epileptiform crises and grave (even fatal) meningo-encephalitis were observed by Marinesco and several others. The authors further cite experimental and biologic studies on the neurotropic power of the virus of venereal lymphogranuloma, pointing out that acute leptomeningitis and meningo-encephalitis have been produced by the virus of venereal lymphogranuloma in certain species of monkeys. In mice the virus has been known to produce, after several passages, a fatal disorder characterized by motor disturbances. In studies on the cerebrospinal fluid of patients with venereal lymphogranuloma, some investigators failed to detect pathologic changes whereas others observed

increased tension, lymphocytosis and positive Pandy and Nonne-Appelt reactions. Investigating the virulence of the cerebrospinal fluid of eight patients with venereal lymphogranuloma, von Haam and d'Aunoy succeeded in two cases in infecting mice by intracerebral inoculation and in carrying the infection through several animal passages. Thus the notion of a clinical neurotropism of the virus of venereal lymphogranuloma, far from having been contradicted by animal experimentation and biologic analysis, has been supported by some of the observations in the course of these studies.

*Treatment of Acute Anterior Poliomyelitis with Cerebrospinal Serum from Convalescing Patients. R. Meyer.—p. 517.

Treatment of Acute Anterior Poliomyelitis.—Meyer reports the use of cerebrospinal fluid from convalescing persons in the treatment of thirteen unselected children in the child clinic of Strasbourg. The children, who ranged in age from 5 months to 5 years (one aged 10 and one aged 12 years), had entered the clinic before the seventh day of their illness and with fever. The first day from 30 to 50 cc. was injected, half intravenously, half intramuscularly. The following two days another injection was made of about 33 cc., in all about 100 cc. The author advises preliminary intravenous injection of a hypertonic solution like sodium chloride in grave cerebral conditions. The author recounts among the advantages of his cerebrospinal serum treatment the facility of lumbar puncture and the possibility of immediate use. It does not induce shock reaction and is easily preserved from spoiling. It is more readily obtained from convalescents than from discharged former patients. It can be extracted from infants every two weeks and if necessary, after the acute stage, every week without danger. To appreciate the therapeutic results obtained, the author explains, one must bear in mind the capricious evolution of poliomyelitis from the point of view of functional prognosis. Functional and vital prognoses are more or less independent of each other except when the localization of the lesion is concerned. The two leading factors that control functional prognosis are the duration of the period of invasion and the time during which paralysis establishes itself. No tabular statement could be set up for this because, the author says, in all cases treated by him with cerebrospinal serum of convalescent patients all evolution ceased in less than twenty-four hours. He thinks that cerebrospinal serums from former patients are not so productive of results as serums from convalescing persons. The author includes in his paper the considerations that first led him to use this serum, his experimentation on animals, his observations antecedent to its use and his method of obtaining the serum.

Condition of Exhaustion Under Influence of Summer Climate in Palestine. W. Kahn.—p. 343.

Studies on Metabolism of Vitamin C: New, Simplified Test of Saturation. M. Vauthey.—p. 345.

Treatment of Supra-Orbital Neuralgias and Headaches.—Strebel says that the ophthalmologist is often consulted for obscure symptoms of the eye in which examination with Javal's ophthalmometer, the refractometer, the slit lamp, the ophthalmoscope and the phorometer disclose nothing abnormal. Palpation of the incisura supra-orbitalis reveals in many of these cases supra-orbital or trigeminal neuralgia. Before treatment is instituted it is necessary to investigate the cause. Not only should a thorough anamnesis be taken but the teeth, ears and nose with the accessory sinuses should be carefully examined and inflammatory processes in these regions should

be treated. Among the various disorders that may lead to supra-orbital neuralgia the author mentions diabetes mellitus and emphasizes that in persistent supra-orbital neuralgia glycosuria should be sought. Other causes are gout, anemia, cachexia, arteriosclerosis, intermittent fever, influenza, typhoid, syphilis and the prolonged action of certain toxins such as lead, mercury, alcohol and nicotine, also rheumatism, colds and psychic shocks. Although the etiologic explanation of supra-orbital neuralgia often brings the effective therapy, it is well known that the customary treatments often fail or require too much time. The treatment suggested by the author consists in the intraneural injection of a 2 per cent solution of procaine hydrochloride with 0.005 per cent of epinephrine. He has used this method in the treatment of neuralgias and neuralgic headaches for the last ten years and has obtained favorable results with it. Two or three injections are generally sufficient. The author also tried the injection of other substances but always returned to procaine hydrochloride with epinephrine as giving the most satisfactory results. Some of the most refractory neuralgias of the head are those which occur in herpes zoster. Here the injection with procaine hydrochloride and epinephrine is not as effective as in the other forms, probably because the neurotropic virus of herpes attacks the nervous substance itself and B vitamins and other factors are necessary for regeneration. However, since the majority of cases of supra-orbital neuralgia can be cured by two or three injections of solution of procaine hydrochloride with epinephrine, the author would not like to dispense with this method.

*Histology of Frei's Reaction. F. Franchi.—p. 369.

Histology of Frei's Reaction.—Franchi found that the lesions induced by Frei's intradermal reaction in patients who are suffering from venereal lymphogranuloma show a typical tuberculoid structure and microscopic aspect. In the tissues examined during the second week after the administration of the Frei antigen there is a predominance of epithelioid cells and of giant cells of the Langhans type over the other types of cells. The author describes the observations of the local nodes or infiltrations induced by intradermal injection of bacterial vaccines in seven patients who were suffering from venereal lymphogranulomatosis and in a normal person (control). All the patients had a strong positive reaction to Frei's antigen. The biopsies were performed within the sixth and fourteenth days after vaccination. The cutaneous reaction was clinically similar to Frei's. The microscopic picture was entirely different. In no case was the tuberculoid aspect observed. The reaction was of the simple inflammatory type. The author therefore concluded that the cutaneous reactions induced by nonspecific vaccines in venereal lymphogranulomatosis are of the Brocq type. They are due to nonspecific hyperergia of the skin in venereal lymphogranuloma. The skin reaction to the Frei antigen, on the other hand, is specific. It shows specific allergy of the skin of the patients and a specific behavior of the skin to Frei's antigen.

Early Mechanical Ileus: Postlaparotomy in Gynecologic Work. A. Salvini.—p. 222.

Conservation of Adnexa in Abdominal Hysterectomy.—Condorelli observed the late results of hysterectomy in eighty-seven cases in which operation had been performed during the years 1932-1937. The cases were placed in two groups. The operation was indicated in the majority of the cases by fibroma of the uterus, simple or complicated with other genital diseases. All the patients were under the age of 40 when they had the operation, which consisted of hysterectomy either alone or in association with unilateral or bilateral adnexectomy (first and

second groups respectively). In a large number of cases in each group the general condition of the patients improved after the operation. The nervous and cardiovascular symptoms of ovarian insufficiency which may complicate the operation were more frequent and acute in the cases in the second group (hysterectomy or hysterectomy associated with unilateral adnexectomy). The libido was conserved in a large number of cases in the first group and in a small number of cases in the second group. Eight patients who had the operation with conservation of the neck and a small portion of the uterus and either one or both adnexa regained menstruation and were the only ones who did not suffer from late symptoms of ovarian insufficiency. The author concludes that the preservation or removal of the adnexa during hysterectomy has proper indications. In general, however, the preservation of the adnexa is of advantage. The best results of hysterectomy are those in which a piece of the uterus (provided with uterine mucosa), as well as one or both adnexa are left in place. Complete removal of the uterus has an unfavorable effect on the nutritional conditions of the ovary. It is followed by symptoms of ovarian insufficiency, which are more acute in bilateral than in unilateral adnexectomy. The development of tumors or of other complications in the adnexa after hysterectomy is rare and it is not related to the operation.

Settimana Medica, Palermo

27: 261-290 (March 2) 1939

- *Bactericidal Power of Total Blood to Several Pathogenic Bacteria from Sulfanilamide Treatment: Experiments. A. Naccari.—p. 267.
Unilateral Metastatic Gonorrheal Conjunctivitis: Case. D. Arcudi.—p. 269.

Bactericidal Power of Total Blood of Rabbits After Sulfanilamide.—Naccari determined the bactericidal power of the total blood of rabbits for certain pathogenic bacteria before and after administration of sulfanilamide. The drug was administered by the intramuscular route in daily doses of from 0.008 to 0.017 Gm. per kilogram of body weight for five consecutive days. The author found that, before administration of any treatment, the bactericidal power of the total blood of rabbits is strong against colon bacilli and Eberthella typhi, moderate against staphylococci, scanty against streptococci and Fränkel's diplococci and nil against paratyphoid B bacteria. After the treatment the bactericidal power of the blood of the animals becomes strong against streptococci, slightly increases against staphylococci and either diminishes or changes not at all for Fränkel's diplococci and for bacteria of the colon, typhoid and paratyphoid groups. The author therefore concludes that the bactericidal action of sulfanilamide against streptococci is specific. He believes that the drug, when it is injected into living animals or man, induces an organic reaction during which it is transformed into a chemical compound of specific bactericidal effect against streptococci.

Archiv für Dermatologie und Syphilis, Berlin

178: 501-606 (March 18) 1939

- Various Modes of Development of Mycosis Fungoides with Special Consideration of Atypical Cases. P. Berggreen.—p. 501.
Studies on Palligen Provocation. H. T. Schreus.—p. 550.
*Carriers of Gonococci. W. Burger.—p. 562.

Osler's Disease. H. Hottenroth.—p. 582.
Influence of Caffeine and Coffee on Cutaneous Temperature and Perspiration Insensibilis. R. Schmid.—p. 593.

Carriers of Gonococci.—Burger applies the term gonococcus carrier only to those persons in whom the gonococci apparently are mere parasites; that is, the gonococci cause no symptoms, in spite of the fact that they have been demonstrated by microscopic examination or by the culture method. If the term carriers of gonococci is restricted to such cases, their number is comparatively small, but in recent times they seem to have been observed slightly more often, probably as the result of more exact methods of examination. The author reviews cases described by other investigators and then describes two of his own observations, both of which proved to be sources of gonococcal infection. Microscopic examination disclosed gonococci in only one of the carriers; the culture method revealed them in both carriers, but only for a short time. That the organisms were truly the causal agents of gonorrhea was demonstrated by means of the fermentation of dextrose and by the fact that they

did not grow in ordinary agar. The author points out that it might be suggested that in both women an attack of gonorrhea had been cured spontaneously; however, he shows that this is not very likely. In the concluding summary he emphasizes that carriers of gonococci are rare, but perhaps more frequent than was assumed hitherto. He thinks that the suspicion that a person is a carrier of gonococci should arise whenever, in spite of careful microscopic examination, gonococci are not detected although they are demonstrable with the culture method. If this is so, the possibility that they are pseudogonococci must be ruled out by the fermentation test and by inoculation into ordinary agar.

*Epidemiology of Streptococcal Diseases. H. Kleinschmidt.—p. 397.

Epidemiology of Streptococcal Diseases.—Kleinschmidt reports that of approximately 100 children who were born in a maternity hospital during the time between Jan. 6 and Feb. 13, 1938, fourteen became seriously ill with streptococcal diseases of various types between the second and the twentieth day of life and eleven of them died. Since some of the nurslings did not show symptoms until after they had been discharged from the hospital and since the symptoms varied, the connection between the disorders was not recognized at first and the etiology remained obscure. Later, however, the connections became clear. Two of the puerperal women developed scarlet fever, one in the maternity hospital and the other one after discharge from the hospital. Studies on the personnel of the maternity ward revealed that, of ten nurses and maids, three were carriers of hemolytic streptococci. A table listing the newborn who contracted streptococcal disorders indicates that six had erysipelas, six suppurating peritonitis and two pneumonia. The three nurslings who survived had erysipelas, which was treated with prontosil. The other three nurslings with erysipelas were hospitalized too late. They died shortly after. The two nurslings with pneumonia, one of whom had also pleural empyema, and the six with peritonitis died. Culture filtrates of hemolytic streptococci that were obtained from the peritoneal pus of three of the children, when injected intracutaneously in a dilution of 1:1,000, produced strong cutaneous reactions neutralizable by scarlatinal convalescent serum; that is, they contained a considerable amount of Dick toxin. The author concludes from these observations that the hemolytic streptococci of scarlet fever may give rise to disorders of a different symptomatology and that the causal organisms of erysipelas do not have a special position.

Adrenal Cortex and Vitamin C in Treatment of Burns.—Einhauser shows that, in burns, intoxication with the products of the decomposition of protein plays an important part. This intoxication leads to conditions which inhibit the exchange between blood and tissues; among others, the adrenal cortex becomes impaired. The author was able to demonstrate in animal experiments the importance of the adrenal cortex and of vitamin C for the cure of burns and so he decided to resort to this treatment in patients with burns. He reports the history of a boy aged 13 who sustained second and third degree

burns that covered 55 per cent of the body surface, the third degree burns covering approximately 30 per cent. The burns were cared for in the usual way but the boy was given also five times daily, at intervals of three hours, injections of adrenal cortex extract and twice daily injections of ascorbic acid. This treatment with adrenal cortex extract and with vitamin C was continued for three weeks. Moreover, blood transfusions were given repeatedly; sixteen were made during the first five weeks. The clinical course was changeable but the patient survived and ten months after the accident the improvement was still progressing. The author thinks that this therapeutic success was at least partly due to the administration of adrenal cortex extract and to the administration of vitamin C. He found the combined administration of adrenal cortex extract and of vitamin C effective in other patients with severe burns and thinks that his experiences justify the use of this treatment on a larger material.

Calcium Therapy in Rhinology.—Jents reports the successful use of a calcium preparation in the clinical treatment of twelve patients. Treatment was both oral and parenteral. The author's purpose was to test the pharmacodynamic value of calcium, which laryngologically has assumed increased significance in various ways as a hemostatic, as regulatory of disturbances of the autonomic system and in checking exudation. Calcium treatments were administered to patients in three different pathologic conditions: 1. Three patients whose anamnesis and blood morphology indicated a high susceptibility to bleeding and on whom tonsillectomy and adenotomy could not be performed without danger. Blood coagulability was successfully conditioned by oral or intramuscular doses of calcium preparatory to surgical operation. Even large doses, the author states, did not cause tissue impairment; on the other hand, doses had to be slowly administered to allow for satisfactory absorption. However, in certain cases calcium treatments failed and surgical intervention had to be abandoned. He suggests that in such cases the calcium therapy be supplemented with a diet excluding meat and foods rich in sodium chloride. 2. In two patients with spontaneous or traumatic epistaxis, intravenous and intramuscular injections of calcium brought favorable results. 3. In seven patients with serious laryngeal or pharyngeal edemas of varying genesis, intravenous or intramuscular applications of calcium in some instances produced almost phenomenal reactions in causing the edema to disappear. The author concludes that calcium was found valuable in conditioning the blood preliminary to surgical operations, in inducing hemostasis in spontaneous and traumatic lesions, and in effective control of acute edemas.

Potassium and Calcium in Maternal Serum and in Fetus.—Winkler and Fritsche studied the potassium and the calcium content in the serum of pregnant rabbits and in the fetuses of rabbits and investigated to what extent these values can be influenced by the administration of calcium lactate and ascorbic acid. They found that the potassium content of the serum is reduced as the pregnancy advances. The concentration of potassium in the embryonal tissues, which indicates the intensity of growth in the fetal and placental tissues,

decreases toward the end of pregnancy. A modification of the potassium-calcium metabolism by the administration of calcium lactate and ascorbic acid could be detected neither in the maternal serum nor in the fetal tissues. Although it has been demonstrated that in case of bone fractures the administration of ascorbic acid results in increased calcium deposits at the site of regeneration of the bone, in the fetal skeleton such an increase in calcium deposits is not observed after the administration of ascorbic acid. The concentration of calcium in the fetal tissue runs parallel with the advancement of the pregnancy and is approximately proportional to the absolute increase in weight. Since the administration of calcium lactate and of ascorbic acid had been found to exert no influence on the potassium-calcium metabolism of the fetus, the authors decided to investigate whether this metabolism could be influenced by depriving the mother animals of calcium as well as of vitamin C. No changes were observed when this was done, and so the authors conclude that it is impossible to modify the intra-uterine development of the fetus by additional administration of calcium and ascorbic acid.

Dietetic Therapy of Polycythemia.—Favorable reaction to diet poor in animal albumin had been observed by Herzog and Kleiner in seven cases of polycythemia several years ago. The patients consumed a daily average of 0.7 Gm. of animal albumin only. The authors observed complete or nearly complete improvement in the number of red corpuscles and hemoglobin content after a short interval. High blood pressure decreased and the spleen became smaller in some cases. Microcytosis ceased and the number of reticulocytes decreased. As soon as the patients' condition improved they were able to follow a less strict diet without ill effects (1 pint of milk, 100 Gm. of cheese, 200 Gm. of fish daily; three eggs or 150 Gm. of veal twice weekly). Since then the authors have observed the good effects of the diet in twelve additional cases. The diet has been followed by favorable reaction in seventeen of the nineteen cases; the blood picture showed no improvement in only two cases. The number of blood corpuscles became normal or near normal in fifteen and subnormal in two cases. Definite decrease of red corpuscles had been noted in many cases at the end of the first, in others at the end of the second or third week, or even later.

Eye Complications in Plasmocid Poisoning. Ya. P. Gekker.—p. 269.

Placental Blood Transfusions in Puerperal Sepsis.—Shpolyanskiy states that, of the seventy-two patients with puerperal sepsis who were treated with multiple transfusions of placental blood, eight died, giving a mortality rate of 11 per cent. Omission from this number of two patients admitted in a moribund condition would reduce this mortality rate to 8.5 per cent. Blood studies in the course of the disease revealed that under the influence of multiple transfusions the usual development of anemia was prevented. The number of erythrocytes in patients not given transfusions falls as low as 1 million or less; in the patients given transfusion the lowest number was 2.2 million, which rose to 4.2 million by the time the temperature returned to normal. The author adopted the following method of treatment: Transfusions of about 100 cc. of placental blood were given every other day, in severe cases

every day, until the return to normal temperature. Massive transfusions were avoided in order not to place too great demands on a debilitated organism. The transfusions may be continued for a long period. One of the author's patients, suffering from a severe hemolytic streptococcus septicopyemia, was given thirty-six transfusions (3 liters), and another patient who had had forty-two chills was given twenty-eight transfusions (2,800 cc.). Both patients recovered. The earlier the transfusions, the better the chance for recovery. Abortive effect was frequently observed when this therapy was begun after the first or second chill or after the second or third day of fever. Cases in which this therapy is delayed frequently go on to formation of metastatic abscesses, particularly in the lungs. Thrombophlebitis, pulmonary infarct, pneumonia and toxic lesions of the kidney do not constitute contraindications to blood transfusions. The effect of transfusions on the course of pneumonias is particularly favorable. The author calls attention to the high biologic quality of the placental blood, its high hemoglobin and erythrocyte content, and the presence of numerous hormones and of calcium salts. From 100 to 120 liters of placental blood was obtained in the course of one year in his obstetric department of ninety beds. This amount was adequate for the needs of the entire gynecologic-obstetric clinic.

Arsphenamine for Amebic Dysentery and Hepatitis.—

Van Wesel says that about ten years ago he discovered accidentally that the intravenous administration of neoarsphenamine will effect cure in cases of amebic dysentery that prove refractory to other treatments. He says that the simultaneous administration of emetine and chiniofon produces much better results than does their successive administration. The intravenous injections of neoarsphenamine he likewise combines with the administration of chiniofon and emetine. A table, which lists his method of medication over a period of ten days, shows that chiniofon is given every day three times in doses of 0.25 Gm.; emetine is given in doses of 50 mg. three days in succession and thereafter on alternate days; neoarsphenamine is injected on the second, fourth and tenth days in quantities of 0.1, 0.3 and 0.6 Gm., respectively. The author says that this mode of treatment was always successful. Regarding the use of arsphenamine in amebic hepatitis, he says that such cases have been comparatively rare in recent years and that he was able to try arsphenamine in only one case of high fever, severe pain and typical enlargement of the liver. Moderate doses of solu-arsphenamine counteracted all clinical symptoms within a few days. However, in a postscript to this report the author says that the patient later had a recurrence of the hepatic symptoms. To be sure, the administered doses were comparatively small and solu-arsphenamine was used, which the author regards as less effective than neoarsphenamine. He thinks that arsphenamine should be given further trial in the treatment of amebiasis.

Hypophyseal Weakness and Subnormal Weight.—

In remarks about Simmonds' disease, Kerppola says that, whereas the literature contains many reports about the completely developed cases of this disease, the milder forms of the disease have received little attention. The author decided to investigate whether symptoms of hypophyseal weakness can be detected in

emaciated persons in whom the subnormal weight cannot be explained by other diseases. He reports studies on forty such patients, whose ages varied between 16 and 45 years. In the anamnestic inquiry attention was given to the appetite, and in the women to the menstruation. In the examination the author determined the height, weight, temperature, pulse and blood pressure. Moreover, the condition of the skin and of the hair was investigated. The sella turcica was studied by means of roentgenoscopy. The basal metabolic rate was determined by means of Krogh's apparatus. The blood was examined for the calcium and chloride content and a complete hemogram was made. The behavior of the blood sugar was determined by means of a tolerance test. Finally, the patients were subjected to a test breakfast and the intestinal function was examined. In the course of these studies it was found that the patients had many symptoms that are characteristic for hypophyseal weakness. About half of the patients had a low sugar tolerance curve, a relative lymphocytosis and low hydrochloric acid values. In approximately one third of the patients a relatively small sella turcica, mild anemia and granulocytopenia were observed. Menstrual disturbances, low stature and low metabolic rates were found in a small number of cases. A complex of symptoms characteristic for hypophyseal weakness was present only in a limited form and only in a small number of cases. The examined material included forms ranging from complete normality, through all transitional forms to the symptomatology of hypophyseal weakness.

*Short Wave Therapy of Rheumatism-like Disorders. A. H. Johansen.—p. 291.
Scarlet Fever-Angina Epidemic Originating from Scarlet Fever-Otitis Media in Milker. E. J. Henningsen and J. Ernst.—p. 298.

Short Wave Therapy of Rheumatism.—Johansen states that short wave therapy has been carried out systematically at the Finsen Institute during the last four years. It has given excellent results in lumbago, ischialgia and rheumatism of the muscles. It has proved useless in spondylitis deformans and osteo-arthritis, with only occasionally a purely palliative effect. In chronic disorders of the joints the method by itself has sufficed only in rare cases, although the palliative results are not to be underrated, but its great value as an integral part of the general treatment of these disorders is emphasized. The results of short wave therapy in twenty-two cases of lumbago, eighteen of ischialgia, forty of rheumatism of the muscles, eight of infectious arthritis and twenty-six of chronic primary progressive polyarthritis are tabulated.

Roentgen Treatment of Ulcers. Kramer-Petersen and A. Wagner.—p. 323.
Case of Acidosis Due to Vomiting of Achyllic Gastric Contents and Sputum. E. Kirk.—p. 328.

Metastatic Hypernephroma in Uvea.—Fledelius says that metastatic hypernephroma in the uvea is extremely rare. In a man now 56 years of age hematuria set in about ten years ago; two years later the left kidney was extirpated and found to be the seat of a typical hypernephroma. After five years a small tumor appeared in the angle of the jaw and somewhat later a similar tumor developed on the right natis; both were removed a year ago. About a year ago separation of the retina of the left eye was established. On enucleation of the eye the suspected metastatic hypernephroma was verified. The tumor, which was situated in the choroid and was of the size of a hazelnut, had not caused increased tension. Diastrophic illumination had afforded no certain information, as the tumor did not contain pigment. Microscopically the extirpated tumors all presented the same general character. The primary tumor as well as the tumors on the neck and the natis were abundantly supplied with blood vessels, the two metastatic tumors suggesting angiomas. There was an angiomatous formation, ascribed to stasis, in the bulbar conjunctiva, a caput medusae corresponding to the more deeply seated tumor in the uvea. During the ten years the patient's condition was on the whole satisfactory.

THE PHYSICIAN AND TUBERCULOSIS

J. ARTHUR MYERS, M.D.

MINNEAPOLIS

Osler's message to the general practitioner on the subject of tuberculosis was:

The leadership of the battle against this scourge is in your hands. Much has been done, much remains to do. By early diagnosis and prompt, systematic treatment of individual cases, by striving in every possible way to improve the social condition of the poor, by joining actively in the work of the local and national antituberculosis societies you can help in the most important and the most hopeful campaign ever undertaken by the profession.

This statement was a challenge to the medical profession at that time but it is a greater challenge now. Since it was made the tuberculosis situation, largely through the endeavors of the medical profession and the National Tuberculosis Association, has changed in magnitude but not in emphasis. The present armamentarium includes sufficient understanding and equipment for control of tuberculosis to the same degree as other contagious diseases have been controlled. The heritage of the present day has come through a long line of physicians and pure scientists who labored in darkness through the centuries, but each torch that was lighted was carried on by others until today the field is well illuminated.

What is really known about tuberculosis?

THE CAUSE

The accumulation of facts and methods made it possible for Koch to discover and demonstrate that the tubercle bacillus is the cause of tuberculosis. Much has been said about secondary causes, such as constitution, body chemistry, dose of bacilli and run-down condition. Such factors as constitution and differences in body chemistry may be of considerable importance in the development of clinical tuberculosis, yet the fact remains that almost nothing is known about them. The development of tuberculosis has often been attributed to a "run-down" condition of the body when in all probability this condition was the result of the developing tuberculosis. The dose of tubercle bacilli may be an important factor, but controlled doses are possible only in the laboratory. Corper has shown that on a medium ideal for the growth of tubercle bacilli from one to ten will multiply to one billion in three or four weeks. Whether human tissue ever constitutes such an ideal medium is not known, but it is known that bacilli proliferate in the body sufficiently to cause death. Suffice

it to say that, regardless of such factors as constitution and body chemistry, tuberculosis never develops in the absence of the tubercle bacillus.

CONTAGIOUSNESS

Several centuries before Christ the contagiousness of tuberculosis was definitely stated. By 1865 Villemin had proved definitely that the disease is contagious. Koch's discovery confirmed Villemin's work and revealed the cause of the contagion. Today it is recognized that human beings cannot live long in contact with open tuberculosis without reacting to the tuberculin test, because of the development of primary complexes. Because of this, epidemiologic methods have been employed on a wide scale with tuberculosis. It is important that physicians report all cases to the local and state health departments in order that sources of infection may be traced and arrangements made for adequate examination of contacts. Likewise, because of its contagiousness, the treatment of the disease by a strict technic for contagion is imperative.

THE DIAGNOSIS

A definite history of known exposure is important, but the absence of such a history is of no value. Symptoms are usually entirely absent or mild until the disease is well advanced. This is also true of physical signs. Laboratory examinations of sputum for tubercle bacilli usually do not reveal them until the lesions are well advanced. Therefore he who depends on symptoms, signs and presence of bacilli in the sputum will detect but little tuberculosis while it is in the minimal stage; in fact, in from 80 to 85 per cent of cases the disease is well advanced before significant symptoms appear. These facts can have only one meaning to the medical profession, namely that tuberculosis must be sought and found among healthy appearing persons if patients are to be treated most successfully and the disease kept from becoming communicable.

Physicians are now equipped to detect tuberculosis within three to seven weeks after bacilli have entered the body and the primary complexes have begun to develop. This is done by the tuberculin test. A tuberculin reaction indicates with a high degree of certainty that a primary tuberculosis complex containing live tubercle bacilli is present in the body. This complex is the first phase in the development of tuberculosis and is tuberculosis. The former conception that tuberculosis is present only when the individual manifests evidences of illness was erroneous. When such evidence is present the patient is entering or already is in the consumptive stage. As no one develops clinical tuberculosis without first having had the primary complex, the first step in the diagnosis is to determine by the tuberculin test whether this complex is present. Since the persons who do not react to the tuberculin

Presented as part of the address of the president of the National Tuberculosis Association at Los Angeles June 20, 1938.
From the Departments of Preventive Medicine and Internal Medicine, University of Minnesota, and the Lymanhurst Health Center, Minneapolis.

test may subsequently be exposed to a carrier or a person with frank tuberculosis, the test should be repeated every year to determine whether a primary complex has developed since the test was last administered. No phase of the examination can possibly substitute for the tuberculin test. It diagnoses accurately the primary tuberculosis complex. Beyond this point it provides no assistance in diagnosis. Any examination that omits the tuberculin test, whether in a physician's office or in survey work, is incomplete.

Having identified a tuberculin reactor, who is by that token a potential subject for the reinfection form of clinical tuberculosis, the physician must seek carefully to determine whether this type is already present in demonstrable form. Chronic reinfection pulmonary tuberculosis develops in children prior to adolescence with such rarity that there is almost no need to carry out the further phases of the examination until this period is reached. When young adult life begins, the physician must seek carefully to determine whether clinical pulmonary tuberculosis is developing in the lungs of tuberculin reactors. Chronic pulmonary lesions usually start in a small way, and for some time no phase of the examination will reveal their location. However, as the disease extends and more reaction occurs in the tissues around it the area becomes sufficiently large and dense to obstruct the x-rays and therefore a shadow is produced on the film and often on the fluoroscopic screen. Such shadows may be found by x-ray examination on an average two or three years before the disease causes symptoms which will bring the patient to the physician for examination. A final diagnosis of tuberculosis cannot be made from shadows cast on single or even on stereoscopic x-ray films, since other diseases cast shadows which in every respect appear the same as those of tuberculosis. Just as the tuberculin test screens out those who have primary complexes in their bodies, so the x-ray film screens from among the tuberculin reactors those who have visible areas of disease in the lungs. The number of tuberculin reactors whose x-ray films reveal shadows which may be due to clinical pulmonary tuberculosis is relatively small in any one year. For example, 4,372 students entered the University of Minnesota in the fall of 1936. The tuberculin test was administered to 4,365, of whom 1,004 reacted. Of these 982 had x-ray films of the chest, among whom only thirteen presented shadows that might have been cast by tuberculous lesions and therefore required complete examination for diagnosis.

When the x-ray film reveals no evidence of disease, examination of tuberculin reactors should be repeated annually, since during any subsequent year tuberculous lesions of a clinical nature may develop. The presence of such shadows at the original x-ray examination or any subsequent examination necessitates a most careful and complete examination to determine whether the shadows are due to tuberculosis and if so whether the disease is progressive and requires treatment or is communicable and requires technic suitable to contagious disease in its management. This phase of the examination may require various laboratory procedures, such as the examination of the sputum and the gastric contents for tubercle bacilli. Even bronchoscopic examinations may be necessary to differentiate between the various diseases. In some cases it is necessary to make a series of x-ray films over a period of weeks or months to determine whether the lesion that casts the shadow persists, decreases or increases in size.

Those which disappear within a month usually are not due to tuberculosis; those which persist two or three months or longer may be due to tuberculosis. Other conditions, such as malignant growth and fungous disease, also cause persistent shadows in the same locations, and these conditions may coexist with tuberculosis. Therefore there is nothing sufficiently characteristic about a single x-ray examination to justify final diagnosis. Nevertheless, the x-ray study is far superior to any other phase of the examination in detecting the location of small areas of disease. If such study is omitted, diagnoses of chronic pulmonary tuberculosis are often postponed until the symptoms of advanced disease advertise its presence.

Drolet has found that the ratio of deaths to new cases of tuberculosis reported in some communities has varied little during the past twenty years. This is not surprising when it is considered that the majority of tuberculous patients still have the disease in the moderate to the far advanced stage when symptoms bring them to the physician for examination. This is due to the nature of the disease rather than to failure of treatment, and with present methods it will continue until the case finding program extends to all healthy persons and the disease is detected long before symptoms appear.

The presence of the primary complex can now be detected within three to seven weeks after it starts to develop, and chronic pulmonary tuberculosis can be located two or three years before significant symptoms appear. Therefore healthy appearing persons must be examined if tuberculosis is to be diagnosed at a time when it can be most successfully treated and before it is communicable.

THE TREATMENT

Every patient whose disease cannot be rendered non-communicable in a short time should be admitted to a sanatorium or a general hospital, either private or public. In 1935 the American Medical Association reported the fact that sanatoriums, tuberculosis departments and preventoriums in the United States represent a total replacement valuation of approximately \$328,937,777.36 and that the annual cost of maintenance of these services amounts to approximately \$75,906,582.41. The fact was also shown that 418 general hospitals in 1935 had tuberculosis departments with a capacity of 14,601 patients and special tuberculosis services were in operation in 322 other institutions, such as those for nervous and mental diseases, with a total capacity of 13,933 beds. In 1934 the sanatoriums and general hospitals admitted 121,706 patients. The directory of sanatoriums of the National Tuberculosis Association shows that in 1938 there were 523 sanatoriums, with a capacity of 74,752 beds.

In at least one state more beds for the tuberculous in sanatoriums and general hospitals are available than are now being used. Yet in some states the number of beds is far below the need. Although tuberculosis in all its phases is definitely decreasing with even the present haphazard methods, postponement of provision for patients with communicable disease simply prolongs the present dilemma. The other communicable diseases which show their disastrous results immediately command quarantine or hospitalization at the time of an epidemic. The same factors hold true for tuberculosis even though the disastrous results are delayed and less spectacular. If the additional beds were needed for

only five or ten years, the money would be well spent. Certainly the pesthouses, long since abandoned because of disappearance of demand for their beds, served a useful purpose in controlling other contagious diseases. The fundamental fact remains that no community can solve its tuberculosis problem until it provides a sufficient number of beds for the immediate isolation of every person with known communicable tuberculosis and every one with unsuspected tuberculosis which may be brought to light by adequate examination of the entire population.

The patient with the reinfection form of clinical pulmonary tuberculosis should be kept comfortable, and the air of his environment should be conditioned to a temperature of approximately 68 F. and a relative humidity of from 40 to 60 per cent in slow circulation, with all contamination removed. Food fads must be discarded and the patient's diet arranged on the basis of bodily requirements. All attempts have failed to find a drug which will disinfect the body of tubercle bacilli. The x-rays have failed to destroy tubercle bacilli in the lungs, and their use in the treatment of pulmonary tuberculosis has been abandoned. Tuberculin as a therapeutic agent has failed to cause the desired results, so that today it is rarely employed. However, desensitization of tissues through the administration of tuberculin in an attempt to prevent necrosis if and when reinfection occurs is being actively investigated. All in all physicians are forced to resort to rest of the diseased organ.

While strict bed rest alone is valuable for the ill person in providing an opportunity to build up a reserve of energy, it does little to rest the diseased lung. Therefore mechanical procedures which provide for localized rest of the area of disease are now in general use. For example, artificial pneumothorax is employed by general practitioners as well as by specialists in pulmonary disease. The indications for this method of treatment include minimal progressive lesions in the bodies of healthy appearing persons as well as advanced lesions. The collapse of the diseased area reduces the oxygen supply of the tubercle bacilli and thus materially interferes with their multiplication. By reduction of the movement in and around the diseased lung on respiration, connective tissue cells are permitted to proliferate more readily, and this process probably is actually stimulated by the collapse, so that walling and scarring off of the diseased area results. The inner walls of collapsed cavities may become adherent, so as to result in complete obliteration of the cavity. By this method long periods of bed rest are often avoided, and in many cases little or no loss of time from work is necessary. For certain selected persons who cannot have artificial pneumothorax because of adhesions, extrapleural pneumothorax is being practiced with apparent success.

When artificial pneumothorax cannot be induced to such a degree as to obtain a satisfactory result, surgical collapse of the lung by such procedures as extrapleural thoracoplasty may accomplish the same end. Only a few years ago one could count on the fingers of a single hand the surgeons in America well qualified to perform major operations on the chest; today they are to be found in all of the larger and many of the smaller cities. Therefore there is no excuse for not giving the advantages of collapse therapy to any patient whose disease indicates it. The financial status of the patient is no reason for postponing the special forms of treat-

ment, since physicians and surgeons today, as has always been true, give freely of their time and skill. It must constantly be kept in mind that collapse therapy does not cure tuberculosis nor does it always prevent subsequent development of lesions in other parts of the body, such as the contralateral lung and the kidney. Collapse only brings about a more favorable condition in and around the area of disease, so that the defense mechanism of the body can control it. Collapse procedures are valuable not only to many patients but to the families and communities, since they often convert the disease from a contagious to a noncontagious stage.

IMMUNIZATION

Enthusiasm for the production of artificial immunity has waxed and waned since 1888, but to date nothing of proved value has been discovered. Any immunity which may develop from the primary complex, even though it harbors living tubercle bacilli for decades, is not dependable from the standpoint of subsequent attacks of clinical disease. Since this is true, attempts to produce immunity artificially through the use of living or dead, virulent or attenuated tubercle bacilli begin with a shaky premise. Therefore at the present moment immunity offers little or no help.

WELL ESTABLISHED FACTS

With modern facilities for diagnosis, treatment and prevention of tuberculosis some definite facts have been established which have produced a greater understanding of the disease. Through animal experimentation and close observation of the same human beings over a long period, the evolution of tuberculosis from the time bacilli enter the body until the disease terminates in death is well known. There is no dividing line between tuberculous infection and tuberculous disease, for every person who reacts typically to tuberculin has the primary complex somewhere in the body. This is the first phase in the development of tuberculosis and is not separated from other phases which are dependent on it.

Two types of tuberculosis are now recognized: The first infection type begins when tubercle bacilli enter tissues not sensitized to tuberculin. It causes but little destruction of tissues, and if symptoms are present at all they are of short duration. Usually the person who has it does not know of its presence unless a tuberculin test is made. The primary complex is the first infection type of tuberculosis. While this type of disease probably at one time developed in the bodies of nearly all children, the situation has been so changed that in many places today not more than 10 or 15 per cent of children have been infected. In the state of Minnesota actual observation has shown that in only approximately 1 per cent of children and young adults do primary complexes develop each year; however, in other parts of the country the rate of infection is much higher. The primary tuberculosis complex is resisted so well by the child's defense mechanism that it requires no treatment whatever. It is true that some infants and children die of tuberculous pneumonia, meningitis and generalized miliary tuberculosis, but these are reinfection forms of the disease. Chronic pulmonary tuberculosis is a rare condition in the child before adolescence; in fact, from the ages of 5 to 15 years illness and death from tuberculosis are almost nil. Excellent evidence to support this statement is to be found in the fact that in 1936 there were in the

United States 24,403,489 children from 5 to 15 years of age. If the rate of infection is only approximately 1 per cent a year throughout the nation and if it is considered that only 10 per cent of these children have the primary tuberculosis complex, 2,440,349 would have reacted to tuberculin. In 1936 there were only 1,807 deaths from all forms of reinfection tuberculosis among children from 5 to 15 years of age; in other words, 99.926 per cent of the infected children tolerated well the primary tuberculosis complex. Only 0.074 per cent had the fatal reinfection type of tuberculosis in this period.

It is now known that treatment has no influence on the primary complex, as the walls form around the bacilli in the same way when the person goes about the usual activities of life as when he is placed on strict bed rest or collapse therapy. Nothing destroys the tubercle bacilli or reduces the allergy of the tissues. Apparently nothing has any influence on the later escape of bacilli from the primary foci. The infant or child with primary tuberculosis on treatment, including strict bed rest, may have meningitis, miliary tuberculosis or tuberculous pneumonia as readily as the one leading an active life. Moreover, the person who has had drastic treatment for the primary complex apparently is just as likely to fall ill later from acute or chronic forms of the disease as the person who has had no treatment for the primary disease. Therefore it is difficult to find any justification whatever for the construction of preventoriums or children's buildings on sanatorium grounds or the further maintenance of those already in operation.

Moreover, since tuberculosis in communicable form is so rare between the ages of 5 and 15 years, there is practically no justification for the making of x-ray films of the chests of children at this age. The huge sums of money that have been expended on surveys among school children to determine this fact were justified but, with the fact determined, to continue such work is a waste of funds.

Since in many parts of the country the majority of children pass into adult life without having had the primary tuberculosis complex, and even if only 1 per cent of the population becomes infected each year, the time has been reached when more first infections occur in adults than in children.

It was formerly believed that the person who was not infected in childhood is in a hazardous position if infection occurs in adult life. Actual observations show that such persons tolerate the development of primary complexes with practically no immediate symptoms or incapacity, just as is true of children. In fact, of several hundred students of nursing and medicine who became infected under my observation only three showed any symptoms that might be due to the primary complex. Indeed, I have not seen the so-called infantile type of tuberculosis develop in a single person who first became infected in adult life; therefore, from my evidence as well as that obtained from the work of others, I am convinced that the first infection type of tuberculosis should be postponed as long as possible.

Apparently there is now general agreement among tuberculosis workers that the ideal situation for the individual or the community is the absence of tuberculous infection, since the reinfection type of tuberculosis is dependent for its development on the presence of the primary complex, which has sensitized the tissues to tuberculo-protein and often provides the tubercle bacilli for the reinfection. The reactions of the tissues to

reinfections with tubercle bacilli, whether from exogenous or endogenous sources, are much more intense than those to first infections, because of the sensitiveness of the tissues to tuberculo-protein. In the areas of disease necrosis is common; this results in cavity formation. Indeed, the reinfection type of tuberculosis causes nearly all of the illness and death from this disease. Through longitudinal studies—that is, observation of the same persons over a long period—it has been found that the child who reacts to tuberculin is more likely to have the reinfection type in adult life, whether or not the location of the primary complex is determined by x-ray film during childhood. In fact, among more than 400 children who reacted to tuberculin and who were observed for ten or more years at the Lymanhurst Health Center, approximately 15 per cent have already fallen ill or died from tuberculosis of the reinfection type. If this situation exists throughout the country one can readily appreciate the seriousness of the primary tuberculosis complex in the human body.

From adolescence on the reinfection chronic form of pulmonary tuberculosis develops in addition to the primary complex. The number of cases increases through the twenties and thirties and indeed the mortality peak is reached during the thirties. Many persons pass into the declining period of life with chronic lesions that may or may not have caused illness. In other persons who have had no evidence of clinical tuberculosis it develops during the declining decades of life. The result is that, after the age of 50, for the number of persons living the incidence of communicable pulmonary tuberculosis is higher than in any other period. Indeed, tuberculosis among the aged is a serious problem, because of both its prevalence and benignity and its communicability.

In recent years attempts have been made to employ case finding on a larger scale than ever before. Tuberculin testing of large groups has been practiced in various places, and many physicians use the test as a routine in their office practice. Indeed, every year millions of tuberculin tests are administered to human beings. To make x-ray films of the chests of such large numbers of persons was an impossibility with the usual equipment. Born of necessity, a new device eliminates the handling of each individual film in exposure, development and interpretation. To save time and cost, rolls of film for the x-ray camera similar to those of the ordinary kodak are now available. A single rapid camera can make a thousand chest exposures a day. The rapid development and viewing of these rolls of films save further time and expense. In fact the film is delivered to the physician ready for interpretation, at a cost of approximately 65 cents, and if the volume of this work is sufficiently increased the cost may be reduced. Moreover, the films are of excellent quality. This method has been approved by large medical societies, and there now appears little doubt that it will extend to the whole nation and completely revolutionize case finding of tuberculosis.

Various methods of finding cases of tuberculosis have been employed. The first was the examination of only the contacts of persons known to have tuberculosis. This was too limited, since many unknown sources exist which may not come to light for years or may even be first detected at autopsy. Another method consists of administering the tuberculin test to all school children and examining the adult associates of the positive

reactors. This is good, but there are persons with tuberculosis in homes with no children of school age. A third method, consisting only of making x-ray films of the chest and arriving at diagnoses in this manner, is to be condemned because from the shadow cast by an area of disease one cannot accurately determine the cause. It is poor economy to make films annually of the chests of 130,000,000 persons when only 65,000,000 or less are at the moment infected with tubercle bacilli. The only possible solution is a careful search for tuberculosis in the bodies of all persons in the community, with every phase of the examination of proved value being used.

Tuberculin tests and x-ray examinations of the entire population of this nation can be done for one half of what is now being spent annually for the hospitalization of patients whose disease was detected by old methods after it had become so advanced that long periods of institutional care were necessary and the patient's best chances of complete recovery lost. Wherever examinations have been made of large groups of healthy appearing adults, the number of cases found has been gratifying.

RESULTS

The accomplishments in the field of tuberculosis over the past two decades have been almost miraculous; in fact more has actually been done to control the disease than in all the centuries of the past, as indicated by the decline in mortality, morbidity and rate of infection. Boynton has shown that in one state where even feeble attempts have been made to protect infants against exposure the mortality from tuberculosis among those under 1 year of age decreased 88 per cent during the eighteen years that preceded 1933. In 1904 in this country approximately 202 persons lost their lives each year for every hundred thousand of the population. In 1937 only fifty-five persons and in some places less than thirty per hundred thousand died from tuberculosis. In some cities and states the demand for sanatorium beds has definitely decreased in recent years. In one city where 47 per cent of the children in grade school reacted to tuberculin in 1926 only 18 per cent reacted in 1936. Similar decreases in the incidence of tuberculin reactors are being reported in other places; in fact tuberculosis has decreased in some parts of this country to such an extent that a regional meeting of the National Tuberculosis Association was held in 1938 to consider methods of accrediting counties and states, such as the veterinarians found valuable.

The veterinarian has aided greatly in the control of tuberculosis both in animals and in man. In all but twenty counties of the nation the incidence of tuberculous infection among cattle has been reduced to 0.5 per cent or less, and in some whole counties the disease has been completely eradicated. This has had a marked influence on certain forms of tuberculosis in man. In one state it has been estimated that fifteen years ago approximately 70 per cent of the patients in hospitals for crippled children had tuberculosis of the bones and joints. A recent survey of all cripples under 21 in that state showed that approximately 3 per cent of their disabilities were due to tuberculosis. It is probable that the control of tuberculosis among cattle has contributed to the decline in the incidence of positive tuberculin reactors among children and young adults.

THE FUTURE

Although the challenge of Osler has been accepted by the medical profession, approximately 70,000 persons lose their lives every year from this disease and many more are incapacitated at all times. Therefore let us proceed with a united front and actually control tuberculosis.

There is no excuse for any physician not being informed on the modern procedures in the control of tuberculosis. The National Tuberculosis Association publishes a pamphlet containing a list of more than a hundred approved books on various phases of the subject. Volumes of state and regional societies as well as a number of special medical journals contain numerous articles on this subject. *THE JOURNAL* constantly keeps tuberculosis before its readers, as indicated by the fact that in 1937 alone it contained seventeen original articles, 169 abstracts and 129 miscellaneous notes, letters and editorials on tuberculosis.

The course leading to the control of tuberculosis is clear. The word control is used deliberately, because such factors as indifference and procrastination will probably make complete eradication impossible, just as has been true of smallpox. If tuberculosis workers proceed with what is known, enlarging and intensifying the program everywhere, tuberculosis should be reduced to a prevalence no greater than diphtheria and typhoid have at present. The procedure is simple and must not be complicated by allowing extraneous and unimportant factors to enter. The more simple it can be kept, the quicker will tuberculosis be controlled. The following procedures directed by the medical profession and carried out by its members in cooperation with closely allied groups and an informed public should suffice:

1. Administer the tuberculin test to every one. Both old tuberculin and purified protein derivative are satisfactory testing materials. Tuberculin is now being furnished free to physicians by many tuberculosis associations and health departments with directions for administration. The test can be administered to several hundred persons in an hour by one physician. Probably not more than 50 per cent of the population of 130,000,000 are sensitized to tuberculin; therefore only 65,000,000 or less would need to be retested annually, and this number should definitely decrease in a few years. Therefore the total cost would not be large.

2. Make x-ray films of the chests of all reactors approaching and beyond adolescence. Approximately 35,000,000 of the population is under the age of 15 years. Both celluloid and paper films are satisfactory in every respect. Paper films in rolls can be prepared for the physician's description of shadows at 65 cents apiece or less. All adult reactors whose films are clear, as well as those who subsequently become reactors, should have films made of the chest annually. No one should attempt final diagnoses from shadows on x-ray film alone; the film simply serves to screen out those who have lesions which may be tuberculous.

3. Make complete examinations of all whose x-ray films present shadows which might be due to tuberculosis in order to arrive at the true diagnosis. These must be performed with the greatest of care, as serious injustice is done by making diagnoses on insufficient evidence.

4. Arrange for an adequate number of beds in private and public hospitals and sanatoriums so that all persons who have tubercle bacilli in the sputum which cannot

be eliminated quickly can at once be removed from their homes. The strict technic for contagious disease should be established whenever patients with communicable disease are treated. It is as important to protect hospital personnel as members of the patient's family from contagious disease.

5. Arrange to treat or keep under close observation all who have tuberculous lesions the progressiveness or activity of which cannot be determined at once, as well as those who have progressive minimal disease in the presymptomatic and precontagious stage. The physician can manage the disease of the majority of such persons in the home.

6. Cooperate in arranging for rehabilitation or reeducation of all tuberculous patients who control their disease and whose previous or anticipated work might be hazardous to their health. Keep all such persons under close observation through frequent periodic examinations after they have resumed the usual activities of life, since tuberculosis is usually arrested, not cured, and is a relapsing disease.

7. Arrange for the protection of citizens against the importation of persons with communicable tuberculosis by providing adequate examinations of all persons entering the country's ports and crossing its borders. Exercise the same precautions for those of other nations by examining adequately this country's citizens before they leave its ports or cross its borders.

8. Support the veterinarians at every opportunity in their efforts to control the disease in animals, because it is transmissible to man. Their past accomplishments merit this and more.

9. Take an active part in local and national tuberculosis associations, the local medical society, the American Medical Association and all other organizations engaged in tuberculosis work. In this manner provision may be made whereby the use of public funds will supplement rather than supplant the practice of medicine.

A heavy responsibility rests on the medical profession. If practitioners now fail to apply their knowledge so as to control tuberculosis quickly, they will bring discredit to the profession. At this moment there exists an opportunity to win another great victory over disease similar to the victories over smallpox, diphtheria and typhoid; this means sacrifice—the kind that physicians made in winning other victories. Let us continue the traditions of the profession in this respect by giving liberally of our time and effort in order to remove the demand for our service as far as the treatment of this contagious disease is concerned. Nothing that the medical profession could do at this time would bring more well merited respect, alleviate more suffering and prevent more untimely deaths than a concerted and successful effort to control tuberculosis.

Experimental Medicine.—The final and practical use of almost all medical science is to maintain health and to combat disease in mankind. It is in the very nature of things that the study of disease, to be effective, must begin as it must end, with disease itself, and that all knowledge applicable to human disease must owe its inspiration, directly or indirectly, to intimate contact with disease as this exists in living man. If the vitality of medicine is to be increased, it must be clearly recognized that there is a fertile science that deals primarily with patients, and this must be encouraged to a more vigorous growth. The science might be called "experimental medicine" if this term had not come to convey too strongly the idea of experiment on animals.—Lewis, Sir Thomas: *Research in Medicine and Other Addresses*, London, H. K. Lewis & Co., Ltd., 1939.

CONVULSIONS IN CHILDHOOD

A REVIEW OF ONE THOUSAND CASES

M. G. PETERMAN, M.D.

MILWAUKEE

In 1932 the first complete classification of convulsions in childhood was presented together with a study of 419 cases.¹ These cases were studied as thoroughly as facilities permitted. A detailed history was obtained of the family and of the patient. Blood counts, urinalyses, spinal fluid examinations and Wassermann tests were made on all patients. Blood chemistry studies, particularly determinations of sugar, calcium and phosphorus, and roentgenograms, including encephalograms, were made when they seemed indicated. Treatment was instituted and the patients were followed as long as possible. A revision of the original classification was presented in 1934 with the addition of eighty-one cases and a correction according to the age at the time of the first convulsion.² An additional series of 500 cases has been similarly studied and a revised classification is here presented based on 1,000 cases.

The frequency of convulsions in young children has long been a subject of great interest. Various theories and animal experimentation have been submitted in attempts at explanation. A survey of the accompanying tables, however, reveals a logical basis for most convulsions and obviates the necessity for theorization (table 1). The young child is subject to certain hazards and diseases. These diseases are characterized by a

TABLE 1.—Convulsions in 1,000 Cases, Total Series

	Per Cent
Acute infection	34.0

Cause not established	5.3

tendency to produce convulsions. Once these hazards have been safely passed, the child is no more susceptible to seizures than is the adult under similar circumstances. The greatest hazard for the newly born infant is his passage through the birth canal. With a normal delivery, from 10 to 12 per cent of all infants suffer some degree of intracranial injury. With a difficult or abnormal delivery this percentage increases to almost 100;³ 15.5 per cent of the convulsions of childhood are due to birth injury or their sequelae.

The next chronologic hazard is that associated with the acute infections (table 2). The respiratory infections and the infectious diseases, not including meningitis, encephalitis and gastro-enteritis, are responsible for 34 per cent of the convulsions in this series. These diseases are much more frequent and usually more severe in children than in adults. Their severity and the undeveloped immunologic response in the child determine the possibility of convulsions in most instances. The pathologic basis for these convulsions has not been established.

Read before the Section on Pediatrics at the Ninetieth Annual Session of the American Medical Association, St. Louis, May 17, 1939.

After six months the rachitic infant is subject to spasmophilia, and this disease produced convulsions in 8.9 per cent of my cases (table 3). When this age period (from 6 to 36 months) is passed, this cause of convulsions is removed. Idiopathic epilepsy next assumes predominance as the causative factor in 23.6 per cent of the cases. Epilepsy has its onset in childhood because it is probably a hereditary constitutional disease.⁴ (The large number of cases of epilepsy in this series of cases may be misinterpreted as the result

of my particular interest in this disease. However, the referred cases of convulsions are equally divided and I feel that the statistics are not weighted with epilepsy.)

Thus cerebral birth injury, acute infection, spasmophilia and epilepsy are responsible for 82 per cent of the convulsions in childhood (table 4). Sixty-six per cent of the convulsions of childhood occur within the first three years of life. Cerebral birth injury, acute infection and spasmophilia account for 58 per cent. They furnish an adequate pathologic basis or explanation for the seizures and do not require the assumption of an instability within the organism or any other theory. In this age period there is a small group of cases, 3.9 per cent, in which the pathologic basis for the convulsions could not be established. Most of these convulsions were associated with high fever but not with any detected infection. The convulsions associated with fever occur at irregular intervals for two or three years in children under 3 years of age and then do not recur. These cases constitute a clinical entity not yet recognized. Evidence has been submitted that they are aborted cases of epilepsy.² It has been demonstrated that convulsions may be produced in a large percentage of kittens by the production of a rapid rise in temperature. Adult cats are not subject to convulsions under similar conditions.⁵ However, animal experiments have shed little light on human convulsions.

Byers and Hass⁶ have provided an explanation for many of the convulsions associated with "gastro-enteritis." These authors found a cerebral venous sinus thrombosis at necropsy in fifty infants who presented an indefinite clinical picture in which the outstanding symptoms were neurologic. The diagnosis was made only at necropsy. However, a certain number of patients with this syndrome must recover. In these the diagnosis cannot be established. The clinical picture is one of nutritional disturbance usually followed after days or weeks by meningeal irritation, fever and convulsions. Undoubtedly a certain number of the convulsions in this series included under the group of 5.3 per cent of cases listed as cause unknown were

due to dural sinus thrombosis following gastro-enteritis. Ebbs⁷ reported eight cases in 1937 and detailed a clinical syndrome similar to that described by Bailey and Hass,⁸ who reported thirty cases.

It is rather singular that in my series of cases none were found to be due to hypoglycemia or hyperinsulinism (table 5). Josephs,⁹ Harris¹⁰ and others have described cases in which the convulsions were apparently due to a low blood sugar. However, no such cases have come under my observation. I have seen six patients in whom the convulsions had been attributed to this cause elsewhere. In these cases I have been unable to demonstrate a consistent hypoglycemia before, during or after a convulsion. Convulsions could not be produced by fasting or with insulin. Repeated dextrose tolerance curves have been normal. Other authors have reported similar experiences.¹¹ It is possible that hypoglycemia, like the alkalosis produced by the Rosett deep breathing phenomenon, will precipitate a convulsion in a child with an organic lesion or an epilepsy. For example, in spasmophilia the administration of calcium or an acute infection may precipitate a convulsion, but these factors must be considered only the immediate precipitating causes. Gibbs and Lennox have stated that, "in two patients who displayed a large amount of petit mal activity, intravenous injection of a solution of dextrose abolished this activity." In these cases insulin produced marked exacerbation of the pathologic activity but sucrose did not have the same effect. "The amount of petit mal activity in these cases tended to be inversely proportional to the level of the blood sugar."¹² These observations do not coincide with my experience that fasting and the ketogenic diet, which induce low blood sugars and a depletion of carbohydrate in the body, are the most effective procedures available to control petit mal epilepsy.¹³

I have seen no newly born diabetic infants in convulsions. I have seen no convulsions in which an allergic reaction could be considered a factor. There are few cases of epilepsy with an eosinophilia in my

carbon dioxide (from 13 to 17 per cent) produced convulsions or twitchings in 64 per cent of forty-two rats. They also state that further experiments indicate that similar results may be expected in dogs.¹⁴

I have previously emphasized the fact that "teething," worms and adhesions of the foreskin or clitoris are not causes of convulsions. Delayed dentition is often associated with rickets. If spasmophilia follows, convulsions may supervene. Thus the delayed dentition and the convulsions are due to the same common cause but bear no other relation to each other.

The medical profession is responsible, if not for the origin, at least for the persistence of the common misconceptions of the causes of convulsions. The physician must realize that a convulsion is only a symptom but nevertheless a serious one which demands a most thorough study of the patient and a determined effort to find the cause. The importance of a complete history cannot be overemphasized. For example, a history of prematurity suggests a 75 per cent possibility of some degree of intracranial hemorrhage or injury.¹⁵ It also connotes a strong possibility of later rickets and hence spasmophilia. A prolonged difficult labor, extreme molding of the head, cyanosis and lethargy, difficulty in nursing or asphyxia pallida suggests a cerebral injury which is a potential cause of convulsions. The convulsions may occur immediately or as long as nine years later. On the other hand, a rapid precipitate labor may cause intracranial hemorrhage with consequent symptoms.

A history of an acute upper respiratory infection or of fever followed after an interval by increased irritability, twitchings, convulsions and increase in skull circumference suggests a subdural hematoma or a meningitis followed by hydrocephalus.

It is sometimes difficult to evaluate the seriousness of the many injuries and falls sustained in childhood. I have seen an infant with a hemorrhage of the middle meningeal artery which resulted from a 2 foot fall out of a hammock onto a lawn. Another infant fell out of

a buggy onto a lawn and sustained a skull fracture. Undoubtedly many falls result in cerebral injury which may escape recognition at the time.

The typical epileptic patient presents the history of recurring grand or petit mal seizures gradually increasing in frequency and severity. Most mothers can forecast a convulsion in the epileptic child by the change in his behavior. This change is usually described as some vague, indefinite peculiarity which has never been verified clinically or by any physical or chemical means. In 1930 Krasnogorski¹⁶ reported that in some epileptics the conditioned reflexes disappeared as long as two days before attacks. Recently it has been demonstrated that the electro-encephalogram reveals variations in tracings for hours preceding a convulsion.¹⁷

A description of the seizure may be of great value in arriving at a diagnosis. The increasing irritability, facial twitchings and then carpopedal spasm in an infant with rickets is typical of spasmophilia. The "locked jaw" and "facies tetanica" with retained consciousness are well known to all who have seen tetanus. The typical grand mal seizure of epilepsy is common knowledge. However, not over half of the children have auras or involuntaries. The "fever convulsions" always develop when the body temperature reaches a certain individual high point. There is no aura and usually when the fever is reduced the convulsion ceases (table 6).

A study of the moving pictures of the various types of convulsions illustrates many points in differential diagnosis which are difficult to describe.

TREATMENT

The immediate treatment of the convulsions presents an acute problem. If there is an associated high fever, cold packs or cool sponges should be used. A cool hypertonic saline enema may also be given. Magnesium sulfate may be used in 25 or 50 per cent solution. If this is not available, sodium chloride or sugar may be used in the same percentage. These procedures are

safe and will keep the mother occupied until further assistance is provided. Probably more harm has been done with hot baths or hot packs than with neglect. When facilities permit, a spinal puncture should always be done. Whether the fluid is under pressure or not, the drainage will be of therapeutic value and the examination of the fluid will be of great assistance in making the diagnosis. The most effective, practical and rapid

treatment of any convulsion, particularly of continuous convulsions, is the prompt administration of chloroform by inhalation. A vial of fresh chloroform should always be available to every physician called on to treat convulsions. While there is an element of danger in its use, the possibilities of harm are not nearly as great as is the injury to the brain resulting from a continuation of the convulsion. Morphine or opium or even chloral may be more dangerous than chloroform if they are improperly used. Opium derivatives should never be used to treat convulsions. They mask symptoms, depress the respiratory center and diminish or stop peristalsis.

After spinal drainage and chloroform, the drugs of choice are magnesium sulfate, soluble phenobarbital and chloral. Magnesium sulfate may be given in 50 per cent solution by mouth or in a retention enema. It may also be given in from 25 to 50 per cent solution intramuscularly or, for immediate action, in 25 per cent

sterile solution intravenously. The dosage will depend on the age and weight of the child. From 60 to 180 cc. may be given by mouth or rectum, from 5 to 20 cc. intramuscularly or from 5 to 10 cc. intravenously. The injection by vein should be given slowly. The dose should be repeated every four to six hours for from twenty-four to forty-eight hours. The anytal preparations are little used. The convulsions associated with high fever may be controlled with cool sponges, packs or enemas. The convulsions of spasmodophilia may be treated with calcium chloride solution by mouth or intravenously.

The aim of immediate treatment for convulsions is to reduce intracranial pressure, remove all irritation and remove the cause when possible. The physician must also keep in mind that a convulsion produces serious injury to the brain. After the convulsion the child should be treated as in every cranial injury with absolute bed rest and quiet for several days. This point is usually overlooked and neglected.

Recurring convulsions present another problem which will not be considered in detail here. In cerebral birth injury, chronic encephalitis and posttraumatic cerebral injury phenobarbital is the drug of choice. In my experience there is no substitute drug. I have observed no instance of habit formation, increased tolerance or permanent injury resulting from its use. In idiopathic epilepsy the ketogenic diet remains the treatment of choice. For petit mal there is no other effective treatment. Most of the reported failures of the ketogenic diet are due to two factors: first, an attempt to treat organic lesions of the brain, and, second, a lack of understanding of the diet which results in a non-ketogenic diet. No physician would ask a dietitian or a nurse to put a patient on a diabetes or a nephritis diet, but I have seen many epileptic patients who have been referred to the diet kitchen for treatment with a "ketogenic diet." The result has usually been failure.

SUMMARY

A convulsion is one of the most important symptoms in childhood. The frequency of convulsions in young children has a definite pathologic basis. Every effort should be made to determine the cause as soon as possible. The first step is a detailed history. The causes of convulsions in a series of 1,000 cases observed in a private and hospital practice were classified. This classification is of value in making a diagnosis. Every convulsion produces cerebral injury. Therefore after the convulsion the child must be kept at rest in bed until entirely recovered.

759 North Milwaukee Street.

ABSTRACT OF DISCUSSION

DR. HENRY F. HELMHOLTZ, Rochester, Minn.: It is important to know what diseases are likely to be associated with convulsions in the various age periods, and it is of value to have the results of Dr. Peterman's experience. Some variations are to be expected with a different series of observations. Dr. Peterman has recorded no instance of hypoglycemic convulsions or those due to acute nephritis independent of uremia or lead poisoning, all of which are bound to occur sooner or later. This does not interfere with the rough estimation of the likelihood of convulsions at various age periods. The group which seems to me to be unusually large is that labeled "acute infection." This is a large group which, like most of the other groups, represents convulsions of unknown origin which an attempt is made to classify more accurately. It is evident that the correlation of convulsions with diseases is not entirely sufficient because it does not really consider the causative factors of convulsions. It has been the experience of many physicians that in infancy, and even later in childhood, a child with latent tetany may have a convulsion with the onset of an acute febrile illness. In the first attack other symptoms of tetany and a lowered blood calcium may be found. In later attacks this may not be present. It seems reasonable, however, to attribute the convulsion to tetany, particularly when all the members of a family are similarly affected. That is one thing which must be taken into account, namely, that tetany as we see it in families that are predisposed to this disease may be prevented by the administration of cod liver oil, and yet acutely, with the onset of an infection, a convulsion supervenes. In other words there may be no definite evidence of tetany and yet we know from experience that these families are susceptible to convulsions at the onset of a high fever. Hypoglycemia too can at the onset of acute illness bring about convulsions, as reported by Josephs. What other factors, such as alkalosis or superhydration, may play a role, is not known. I am not as optimistic as the author when he says that a survey of the tables reveals a logical basis for most convulsions and obviates the necessity for theorization. We are still far from that point. I have been interested in epilepsy for many years and I am still at a loss to know what causes a convulsion. One other matter, that of therapy. I wonder whether there is the indication for a spinal puncture in all cases of convulsions associated with a febrile onset. In 34 per cent of Dr. Peterman's series, convulsions were associated with acute infections, not of the brain or meninges, so of questionable diagnostic or therapeutic value. In addition to the drugs mentioned, I think the reported experience with dilantin makes it deserving of mention.

DR. H. R. CODDER, Los Angeles: Dr. Peterman's paper will be of interest to everybody who has to treat children for epilepsy. It has been of unusual interest to me because of my attempt to solve some of these problems that we have had for ten years in Los Angeles, in the Children's Hospital, where we have a series of about 600 patients. The part that appeals to me most is the analysis of causes. This is more than a statistical table. It is of real help. I try never to forget that the questions parents want answered are, first, how did my child get this thing? Second, what is going to become of it? We get help from inspecting these tables of causes as they are presented for different ages. We can satisfy ourselves as to what are the causes, but more useful is the way the parents

can be answered as to the prognosis. When the child is 3 or 6 months old, in this age of hazards of childhood, we can say to a parent "The most likely things your child has are things that can be cured, and if the primary disease can be cured, then the convulsions that go with it can be cured." This is one thing at 3 years of age and quite another at 16 or 12 years of age, when idiopathic epilepsy becomes the majority in diagnoses. I would question the diagnosis of spasmophilia in such a high percentage of cases. I do not see it in Los Angeles. I asked a number of my colleagues if they were seeing much spasmophilia and they said they had not seen any for a long time. I too have seen only one or two cases of hypoglycemia. I feel with Dr. Peterman that phenobarbital and dilantin are the most useful forms of treatment. Dr. Peterman could have mentioned other things of interest, for example the emotions of the young child, the training and boarding out of cases and neurosurgery. I congratulate Dr. Peterman on the scope and understanding of this paper.

DR. CLIFFORD SWEET, Oakland, Calif.: I agree with Dr. Peterman that acute infections with high fever play a large part in causing the convulsions which a child experiences for one or a few times and then no longer has convulsions if he is properly taken care of or arrives at a later age. When a child does have an acute convulsion for which the cause is not immediately apparent or in which there is probably an apparent cause, such as an inflamed throat and high fever, I think physicians should be especially careful not to use the word "epilepsy" to that poor mother. Let's not use that term when we speak to the mother about the acute convulsion which has no great chance, at least, of being epilepsy. I think also we should not emphasize the inherited phase of epilepsy. I think the tendency to have epilepsy, the tendency to have convulsions, the tendency to have heart disease or lung disease or any other kind of disease, runs in certain strains of human beings. Supposing a child has had a serious birth injury, and one of the sequelae of that is convulsions. Should that child's parents be told that he is, by inheritance, a defective individual and that therefore their other children may be passing on a defective strain of heredity? I don't think so. I don't know the cause of epilepsy any more than the rest of you do, but I am convinced it is often based on some kind of injury, perhaps from disease. A convulsion, Dr. Peterman has told us, is in itself injurious to the child, and I am certain it is. Therefore when we see a child who has a convulsion we should use every means in our power to prevent that child from having another convulsion. The intelligent mother can generally notice that the child is showing signs which she learns to recognize as the prodromal signs of a convulsion, and that is the time for her to start hydrotherapy, a deep, warm, comfortable bath, a warm, wet pack. There is one trick about a warm, wet pack. If you put a child on the verge of delirium on a warm, wet pack and bind his arms to the sides of his body, he will fight like a wildcat. If you leave his arms free and put the wet pack over the rest of him, he won't mind in the least. I have found ethyl chloride the best means, I think, of relieving the convulsion immediately. The means of prolonging sedation that I think is most useful is one of the barbiturates. After I know the child's tolerance for sodium amytal, if the mother is intelligent and reliable I leave in her house some suppositories or capsules of sodium amytal which she may insert in the child's rectum the next time a convulsion threatens. Roughly, a child can take half a grain of sodium amytal by rectum for each year of his age with safety.

DR. M. G. PETERMAN, Milwaukee: My attempt at classification is not an attempt to explain the physiologic basis or mechanism of the convulsion. I am not able to do that, and I feel, as the other gentlemen do, that the exact mechanism of the convulsion is unexplained. But I did classify the diseases with which the convulsions were intimately associated. There are cases of acute hemorrhagic nephritis in this series, but they are listed under the acute infections. The question of hypoglycemia remains to be settled. Often children are seen with hypoglycemia, with blood sugars of 60 or 70, and certainly in children who are vomiting, who miss meals, frequently the blood sugar gets down to 60 or lower, who do not have convulsions. The child who has convulsions when his blood sugar gets down must have a lower threshold for convulsions, and that must be due to some other cause. There may be some question about

the advisability of routine spinal puncture, but if one can make an early diagnosis of meningitis or of juvenile dementia paralytica or tabes with the spinal fluid one is hesitant to let this important diagnostic measure go in any case. As for dilantin, I have used it for a year. I did not mention it because I seem to be among the few who have not had favorable results. In my experience dilantin has not been satisfactory, and when I have not changed my patients back to phenobarbital most of them changed back themselves. These cases of spasmophilia represent established cases in which there were low blood serum calcium and increased phosphorus. I did not believe there was infantile tetany until a few years ago, when we began demonstrating cases in which the serum calcium was low, cases which responded to treatment and in which there were no convulsions after the calcium was brought to normal. The diagnosis of epilepsy is, to me, always a temporary, provisional diagnosis. Subsequently, something may develop in the history or in the examination which would cause me to change the diagnosis any time there is evidence of organic disease and thus leave the diagnosis of idiopathic epilepsy a diagnosis made by exclusion. The importance of the hysterical element or psychic element in convulsions is difficult to estimate. I think it would be better never to accuse a child of hysteria, and make a mistake occasionally, than to attempt to make the diagnosis. There is no question that an epileptic child may have a seizure precipitated by any number of psychic factors or emotional disturbances. Particularly the child with petit mal may have a whole series of seizures precipitated by an unpleasant experience, but there is a basic cause behind it all, and that is an inherited constitutional inferiority as mentioned by Dr. Sweet.

PROTAMINE AND ALLERGY

- I. NATURE OF THE LOCAL REACTIONS AFTER INJECTIONS OF PROTAMINE ZINC INSULIN
- II. INDUCTION OF SENSITIVITY TO INSULIN BY INJECTIONS OF PROTAMINE ZINC INSULIN

RICHARD A. KERN, M.D.

AND

PAUL H. LANGNER JR., M.D.

Professor of Clinical Medicine and Assistant Instructor in Medicine,
Respectively, University of Pennsylvania School of Medicine

PHILADELPHIA

The injection of protamine zinc insulin for the treatment of diabetes is followed in some patients by redness and swelling at the site of injection, sufficiently severe at times to lead them to discontinue the use of protamine zinc insulin. It therefore seemed desirable to investigate the nature of these reactions, especially from the standpoint of a possibly allergic mechanism. We here record our observations as to the causes and report a new observation, the induced sensitization to insulin which occasionally appears to follow the use of protamine zinc insulin.

SENSITIVITY STUDIES

The first part of this paper deals with the results of intracutaneous tests with protamine. The test material used was a solution of protamine in Coca's solution in a concentration containing 0.1 mg. of nitrogen per cubic centimeter. The tests were performed by the intracutaneous injection of 0.02 cc. of the test solution on the flexor surface of the forearm, the reaction being read in fifteen minutes.

With three diabetic patients who had complained the most of trouble at the site of injections of protamine zinc insulin, tests were also performed by injecting a larger amount, 0.05 cc., of the test solution and reading

The protamine used in our tests and experiments was furnished by Eli Lilly & Co.
From the Allergy Section, Division of Medicine, of the Hospital of the University of Pennsylvania.

the reaction also after twenty-four hours. The test subjects included (a) 104 consecutive diabetic patients who were or had been receiving protamine zinc insulin in daily amounts ranging from 5 to 100 units and for periods ranging from one week to eighteen months, (b) 100 nondiabetic, presumably normal controls and (c) eight allergic persons who in the course of routine testing had been found skin sensitive to salmon protein. It is noteworthy that of the 104 diabetic patients seventeen experienced sore arms or legs after injections of protamine zinc insulin, because of which four had discontinued this treatment.

There was no positive reaction in any subject of the three groups tested intracutaneously with a protamine solution containing 0.1 mg. of nitrogen per cubic centimeter.

It appears therefore that sensitivity to protamine could not be invoked as an explanation for the local reactions experienced by the seventeen diabetic patients from injections of protamine zinc insulin. It is also evident that protamine differs sufficiently in composition from salmon muscle protein extract as to be unable to provoke an intracutaneous reaction in persons known to be sensitive to such extract.

These observations are in accord with what one would expect in the light of existing information: The protamines¹ are sulfur-free, strongly basic substances, rich in nitrogen and of high molecular weight. They consist chiefly of diamino acids (up to 90 per cent of the total nitrogen is diamino acid nitrogen), mainly arginine. They occur in the spermatozoa of many fish species, where they are bound to nucleic acids. The protamine bases are easily soluble in water, give the biuret reaction and do not coagulate on boiling. The protamine salts are precipitated by the alkaloidal reagents (phosphotungstic acid, sodium tungstate).

Salmine is the protamine obtained from salmon sperm. On hydrolysis it yields arginine (87 per cent) and several other amino acids, none of which contain the phenol ring. We found that a weak aqueous solution of salmine was not precipitated by half-saturated ammonium sulfate solution but was precipitated by saturated ammonium sulfate solution.

Taylor² found no evidence of antibody formation in rabbits inoculated with the protamine of salmon sperm.

Wells³ stated that "the protamines, which consist chiefly of complexes of diamino acids with but a small total quantity of a few of the monoamino acids of proteins, are devoid of antigenic activity. This fact also suggests that the diamino acids are not of importance in respect to antigenic function."

It seemed wise, however, further to test the possibility of the antigenic capacity of protamine by attempting to produce sensitivity experimentally.

GUINEA PIG EXPERIMENTS

One guinea pig was given an intravenous injection of 1 cc. of a solution of 2 mg. of protamine (salmine) in sterile water. The animal experienced no obvious toxic symptoms. Three guinea pigs were given intraperitoneal injections of 1 cc. of a solution containing 2 mg. of protamine in sterile water, without experiencing toxic symptoms. All four guinea pigs were given

two additional injections of 2 mg. of protamine at three day intervals. Two weeks after the last intraperitoneal injection each guinea pig was given an intravenous injection of a solution of 1 mg. of protamine in sterile water (0.5 cc.) in an attempt to produce anaphylactic shock. This injection was given without the aid of an anesthetic, lest the anesthesia have an antianaphylactic effect. In no instance was there any evidence of resultant anaphylactic shock.

It is pointed out that the dose of protamine used in attempting to produce sensitivity in the guinea pigs proportionately far exceeded the amounts of protamine used in treating diabetic patients.

THE NATURE OF LOCAL REACTIONS AFTER INJECTIONS OF PROTAMINE ZINC INSULIN IN DIABETIC PATIENTS

Of 104 consecutive diabetic patients being treated with protamine zinc insulin, seventeen complained of local reactions at the site of injections. For the most part these reactions were slight, consisting of moderate redness and induration at the site of the injection and lasting a few hours. Sometimes, however, the reaction was more severe, persisting as long as several days and causing considerable discomfort. Four patients refused further injections for a time. It was next attempted to trace in each of the seventeen cases the possible cause for the reactions experienced.

In practically all instances it was observed that the local reaction followed the first injection of protamine zinc insulin. This proves that the reaction could not have been due to a sensitivity induced by preceding injections of the material.

In three cases it was observed that the local reaction occurred only after some injections, not after all. Obviously, were the reaction due to sensitivity it would have followed every injection.

In four cases in which reactions were experienced only after self administration of the protamine zinc insulin, it was found that the injection, instead of being subcutaneous, was actually made into the superficial layers of the skin. When the same patients were given injections subcutaneously by a physician or a nurse, no reaction resulted.

Careful questioning of eight additional patients suggested that a too superficial injection was probably a factor in the reactions which they experienced from their earlier injections. All eight eventually experienced no reactions from the subcutaneous injections which they were receiving daily during ten or twelve months.

Another possible factor in causing local reactions in some of the last-mentioned eight cases was the use of alcohol instead of boiling as the sterilizing agent for the hypodermic outfit. It should be emphasized that patients must be specifically warned against sterilization with alcohol of needle and syringe.

Yet another cause for a local reaction in one of these eight cases was infection, traced to gross error in aseptic technique.

One patient had left the clinic and could not be traced.

In the remaining case the local reactions differed from those in the other sixteen in that they occurred promptly after injection, as would be the rule with an allergic response, and were attended by purpuric lesions at the site of injection. The reactions had, however, first been noted with old insulin and before the begin-

3. Wells, H. G.: *The Chemical Aspects of Immunity*, ed. 2, New York, Chemical Catalog Company, 1929, p. 28.

ning of treatment with protamine zinc insulin. The patient was tested intracutaneously with beef insulin, with pork insulin, with protamine zinc insulin and with protamine alone. There were prompt and decided reactions with beef and pork insulin, a lesser reaction with protamine zinc insulin and a negative reaction to protamine. The reactions were therefore due to insulin sensitivity, which had developed during insulin treatment and before the use of protamine.

It is of interest to note that the nonthrombocytopenic purpura was an allergic manifestation of the insulin sensitivity.

PROTAMINE AND THE DEVELOPMENT OF INSULIN SENSITIVITY

Since studying the aforementioned group of patients, we have encountered two diabetic patients in whom the use of protamine zinc insulin was followed in from five to eight days by the development of true sensitivity to insulin:

CASE 1.—J. L., a Jewish man aged 64, in whom diabetes developed when he was 50 years old, received insulin periodically for eight years without experiencing any difficulties. June 10, 1938, treatment with protamine zinc insulin was started, 10 units once a day. For a week he experienced no untoward effects, but on the eighth day and thereafter there occurred immediate and marked local reactions with redness and wheal formation at the site of injection and generalized urticaria. An intracutaneous test with protamine zinc insulin gave a weak local reaction. Intracutaneous tests with beef insulin, pork insulin and crystalline insulin all gave typical strongly positive reactions, showing that he was sensitive to the crystalline insulin itself.

CASE 2.—Mrs. C. T. A., a diabetic patient aged 54, admitted to the hospital June 25, 1937, in the service of Dr. T. Grier Miller, during the first five days after admission received from 40 to 50 units of insulin daily without experiencing any local reactions. June 29, 1937, treatment with protamine zinc insulin was begun in a dose of 30 units once a day. After five days the injections were followed by immediate reactions at the site of injection, growing progressively worse after each dose, so that the use of protamine zinc insulin was discontinued and treatment with insulin substituted. Nevertheless the immediate local reactions continued to occur at the site of injection, decreasing slightly in intensity during the weeks that followed. November 10 the patient was tested by intracutaneous injections with beef insulin, pork insulin, protamine zinc insulin and a plain protamine solution. The reaction to protamine was negative, but moderately positive reactions to beef and pork insulin and strongly positive reactions to protamine zinc insulin were obtained.

In addition to our two cases, we have knowledge of one further case in which insulin sensitivity developed soon after the substitution of protamine zinc insulin for insulin.⁴

In these cases it is strongly suggested that the addition of protamine to insulin was in some way responsible for the development of true sensitivity to insulin.

There is evidence to show that the addition to a true antigen of a substance itself possessing no antigenic properties makes it easier to sensitize an animal to that antigen than by the injection of the antigen alone. Harrison⁵ found that guinea pigs could be fairly easily sensitized to ragweed by means of an alum-precipitated ragweed pollen extract. Caulfeild, Brown and Waters⁶ had experienced difficulty in producing high

degrees of sensitivity to ragweed in guinea pigs with ragweed extract alone, less than 10 per cent of the animals having fatal anaphylactic shock on reinjection. When they used an alum-precipitated ragweed extract, every guinea pig acquired a high degree of sensitivity and over 70 per cent died of anaphylactic shock on reinjection. Caulfeild and his associates suggested that this might have been due to the delayed absorption and the consequently prolonged action of the insoluble alum precipitate of ragweed.

There appears to be a certain analogy, although by no means a complete parallelism, between the alum-ragweed method of inducing ragweed sensitivity in guinea pigs and the possible induction of insulin sensitivity by injections of protamine zinc insulin. In each instance, the antigen (ragweed, insulin) is rendered insoluble and its absorption time prolonged. The ragweed precipitate, however, is highly insoluble, taking weeks to be absorbed, and the guinea pig is rather easily sensitized; consequently ragweed sensitivity, and one of high degree, usually results. The insulin precipitate, on the other hand, is only relatively insoluble, being absorbed in from twelve to thirty-six hours, and man is not nearly so easily sensitized as is the guinea pig; consequently insulin sensitivity, while it may develop more often after injections of protamine zinc insulin than after injections of insulin alone, is induced only rarely.

The fact remains that such induction of insulin sensitivity does follow the use of protamine zinc insulin, and in persons whom injections of insulin alone had failed to sensitize. The possibility of the development of insulin sensitivity during the use of protamine zinc insulin should therefore be kept in mind by physicians treating such patients.

SUMMARY AND CONCLUSIONS

1. Local reactions at the site of injections of protamine zinc insulin are sufficiently frequent (occurring in 16 per cent of our series of cases) to assume some clinical importance.

2. These reactions are probably not due to sensitization to protamine, because we obtained negative intracutaneous reactions with a protamine solution in 104 diabetic patients treated with protamine zinc insulin and in eight allergic nondiabetic patients who were sensitive according to cutaneous tests to salmon muscle protein.

3. This is in keeping with existing knowledge that protamines have no antigenic properties and is further confirmed by our inability to induce sensitivity to protamine in guinea pigs.

4. The reactions appear to be due to errors in technique of injection: (a) usually a too superficial (i. e. intracutaneous) injection of the material, (b) at times irritation by alcohol when that substance has been used to sterilize the hypodermic outfit and (c) occasionally to infection, the result of faulty aseptic technic. The errors have occurred as a rule when the material was injected by the patient himself.

5. Two patients became sensitive to insulin five and eight days respectively after protamine zinc insulin was substituted for insulin in the treatment of diabetes.

6. It is suggested that the insulin sensitivity was induced as a result of the more prolonged action of the antigen (insulin) in the course of its slower absorption from a precipitated state.

CHRONIC BRUCELLOSIS IN
CHARLOTTE, N. C.

REPORT OF CASES

FRANK H. ROBINSON, M.D.

AND

ALICE C. EVANS, M.D.

Consultant and Senior Bacteriologist, Respectively, National Institute
of Health, United States Public Health Service
WASHINGTON, D. C.

That brucellosis is a disease of protean manifestations was recognized by Hughes¹ in his classic description. Simpson,² Gentry,³ Hardy,⁴ Bierring⁵ and Woodward⁶ have described its varied symptoms more recently. Hamman and Wainwright⁷ emphasized the importance of considering brucellosis in cases of unexplained pyrexia. Parsons and Poston⁸ recently described four cases of brucellosis in which lymphadenitis was the outstanding feature. One case terminated fatally, and a detailed description of the postmortem observation was given. Every writer on the subject of brucellosis emphasizes the difficulty of diagnosis.

In general, brucellosis may be divided into two clinical types, the acute and the chronic. In the acute type the onset may be sudden or gradual; the fever tends to be intermittent or undulating. Chilliness is common; often there are actual rigors with drenching night sweats. Joint and muscular pains, anorexia with loss in weight, splenomegaly and leukopenia with relative lymphocytosis are common. These signs, together with the presence of a high agglutinin titer, may form a fairly characteristic clinical picture. The cases to be described illustrate the paucity of signs in the chronic disease.

Evans⁹ recently reviewed the literature on chronic brucellosis, and Meyer¹⁰ directed attention to the latent types of *Brucella* infection. These authors and others cited by them have brought forth evidence indicating that the chronic and latent types of infection are more common than is generally recognized. In an earlier paper Evans¹¹ called attention to the analogy between the mild chronic form of the human disease and latent infections in apparently healthy cattle, goats, hogs and other domestic animals.

Huddleson¹² observed that in children the acute type of brucellosis is rare and the chronic type more common. This fact, together with the infrequency of a

good titer of agglutinins in infected children, may account for the impression that children are immune. Anderson and Pohl,¹³ Pray¹⁴ and Dietrich and Bonyng¹⁵ have described the mild type of the disease in children.

On account of the evidence summarized elsewhere⁹ that chronic brucellosis may be a common disease, the National Institute of Health planned several field investigations to obtain data which might give information on its incidence. As a part of the general program, the senior writer conducted a field investigation of the subacute and chronic forms of brucellosis in Charlotte, Mecklenburg County, N. C., during the summer and fall of 1936.

Charlotte, located in the southwestern part of North Carolina, is an industrial and dispensing center, with dairy farming, tobacco and corn raising in the surrounding country. This city, of approximately 107,000 inhabitants, was chosen as one of the survey areas because 81 per cent of milk was sold raw and the herds of cows supplying milk to the city were known to be infected with contagious abortion.¹⁶ Previous to the survey only seven cases of brucellosis had been recognized in Charlotte.

Simultaneously with the survey of human brucellosis, a survey of the disease in the cattle of the vicinity was carried on under the direction of Dr. A. A. Husman of the United States Department of Agriculture and Dr. William Moore of the North Carolina Department of Agriculture. Their survey was a part of the extensive program of the United States Department of Agriculture for the eradication of Bang's disease in cattle. It was their practice to test each herd every month by means of the agglutination test, eliminating positive reactors until the herd was free from Bang's disease. Thereafter follow-up tests were made three or four times annually. In the original tests on 4,096 cows, 15 per cent were found to be positive reactors. In subsequent tests the figure reached 23 per cent. Thus the percentage of reacting cows in the vicinity of Charlotte was higher than the average of about 14 per cent in infected herds reported by Wight¹⁷ for the United States as a whole.

In a survey of human brucellosis, the possibility of infections contracted from hogs and goats as well as from cattle must be considered. The variety of the causal organism which infects hogs (*Brucella suis*) and the variety which infects goats (*melitensis*) are more virulent for man than the variety which most commonly infects cattle (*abortus*). That cattle may become infected with the caprine variety and transmit the disease to man was shown by Taylor, Vidal and Roman¹⁸ and Meyer and Eddie,¹⁰ and that cattle may become infected with the porcine variety and transmit the disease to man was shown by Atwood and Hasseltine¹⁹ and Beattie and Rice.²⁰ That brucellosis may be contracted by the ingestion of infected cow's milk has been

shown by Carpenter and King,²¹ Hardy,⁴ Dooley,²² Hasseltine and Knight,²³ Wilcox,²⁴ Starr and Maxcy,²⁵ Cameron and Wells²⁶ and Johns, Campbell and Tennant.²⁷

Dr. Husman reported that two lots of hogs and two lots of goats in the vicinity of Charlotte were tested and found free from infection. Moreover, none of the subjects of our study had a history of having used goat's milk, and none had contact with either goats or hogs. Nevertheless, studies of the infection in human beings showed that the caprine and the porcine varieties of *Brucella melitensis* may be the causal agents of human infections in the vicinity of Charlotte. Both Evans²⁸ and Poston²⁹ found evidence that in a large proportion of cases in human beings in this area the infection is with the caprine type of the organism (*Brucella melitensis*). A number of the patients in Charlotte were found to have agglutinating titers high enough to produce satisfactory agglutinin absorption reactions. Evans²⁸ studied serums from seven of these patients and found that in five of them (71.4 per cent) *melitensis* antigen absorbed the agglutinins completely, but an *abortus* antigen failed to absorb all the specific agglutinins, indicating that the infecting organism was *Brucella melitensis*. Poston²⁹ cultivated *Brucella* from five of the patients in Charlotte. The organisms were identified by means of the agglutinin absorption and bacteriostatic dye tests. The strains from three patients were of the *melitensis* variety, from one of the *suis* variety and from one of the *abortus* variety. Since none of the patients had contact with goats or hogs and all drank raw milk from infected herds of cows, the circumstantial evidence suggests that some of the cows supplying milk to Charlotte may be infected with the *melitensis* or *suis* variety. As yet there has been no opportunity to make a bacteriologic study of infected cattle in the vicinity of Charlotte.

The survey was conducted among the urban population, with *Brucella* contacts generally limited to the ingestion of milk and dairy products. The search was made chiefly among patients suffering from chronic unexplained ill health, particularly among those with long continued low grade fever. A few patients with psychoneuroses and a few who had had unexplained abortions were included. The opportunity to get in touch with suitable patients was provided by local physicians in response to the request of the field worker (F. H. R.) to be permitted to assist in a study of cases of obscure disease. Although 325 cases were studied, the survey of the city was incomplete because it could cover only that portion of the population financially able to employ physicians capable of making the necessary expensive examinations for a differential diagnosis in the case of a mild disease of obscure origin. Hence not only was the survey incomplete but the group studied

was not representative of the entire locality. Less than 10 per cent of the patients belonged to the lowest third of the population in terms of income and living conditions. Moreover, among the patients with chronic disease who were examined there may have been some with brucellosis which failed of recognition.

The cases were chosen for study because they presented clinical pictures suggesting brucellosis without regard to whether or not specific tests gave positive reactions. Therefore this group differs from groups of cases of brucellosis usually reported. As a rule, other observers of chronic brucellosis have considered the patient's complaints as due to *Brucella* infection only after positive results of laboratory tests have prompted an investigation. This approach tends toward overestimation of the diagnostic value of laboratory data in cases of the chronic disease. The inadequacy of the specific tests was discussed in an earlier paper.

CLINICAL STUDY

The following diagnostic procedures were used: history taking, physical examination, x-ray examination of the chest, urinalysis, hemoglobin determination, erythrocyte count, total and differential leukocyte counts, agglutination tests with *Bacterium tularensis*, *Brucella abortus* and *Brucella melitensis* antigens, opsonocytophagic test, cutaneous test with a 1:10,000 dilution of Huddleson's brucellergin and, with children, cutaneous test with tuberculin (0.1 and 1 mg.). Evans⁹ has described the techniques used for the specific tests. In a few cases cultural studies were made; they were reported by Poston.²⁹

Among the 325 cases studied in Mecklenburg County, a definite or probable diagnosis of brucellosis was made in twenty-two. The cases may be divided into three groups: 1. In five cases the causal organism was obtained from the blood and the diagnosis was regarded as proved. 2. In nine cases the tentative diagnosis of brucellosis, made on clinical bases, was supported by a positive agglutination reaction. (In four cases the titer was 1:160 or higher, in three cases it was 1:80 and in two cases it was 1:40.) 3. In eight cases a diagnosis of probable brucellosis was made despite the fact that specific tests failed to confirm the clinical evidence of *Brucella* infection. The summarized data on all twenty-two cases were given in a previous paper.³⁰

CASES IN WHICH THE CAUSAL ORGANISM WAS OBTAINED

Cultural examinations and inoculations of guinea pigs were made only in cases in which physical signs of disease and a significant agglutinin titer were absent but the history was suggestive of chronic brucellosis. Thirteen such cases were chosen for bacteriologic examinations, and positive cultures were obtained in five. The techniques used and the results of the examinations were recently reported by Poston.²⁹ In the cases in which positive cultures were not obtained, there was no opportunity to repeat the bacteriologic study. All five cases in Charlotte which were proved culturally to be of brucellosis are described here in detail.

CASE 1.—History and Examination.—M. C., a nurse aged 26, referred by Dr. Andrew Blair, when first seen, in July 1936, had as her chief complaints low grade fever, weakness and pains in the joints of four months' duration. The family history was irrelevant. Heretofore the patient had been in good health, having had only the usual childhood diseases. The menstrual history was normal. In an accident in December 1934 she had

suffered fractures of five ribs on the left side; recovery was uneventful. In the summer of 1935 she began to have attacks of jaundice associated with nausea without vomiting. These attacks occurred every few weeks, at first lasting only a few days, but, beginning in December, the jaundice persisted, unaccompanied by any other symptoms, until the onset of the present illness.

This illness began abruptly March 14, 1936, with a sudden chill followed by a temperature of 103 F. and night sweats. The patient was admitted to the hospital, where the chills and fever recurred daily for three weeks; weakness, headaches, anorexia and loss of weight were present for about six weeks. During two weeks of the hospitalization the patient was intensely jaundiced. She received two blood transfusions. Five weeks after the onset she returned home. She was weak and continued to have an afternoon elevation of temperature to 99.5 or 100 F. Finally the joints of her extremities became involved in arthritis, with pain on motion, redness, increased local heat and tenderness. The involved joints were chiefly those of the upper extremities: the middle phalangeal joints, wrists and shoulders. There were occasional headaches, chilly sensations, anorexia, insomnia and some tendency toward depression and irritability.

After leaving the hospital the patient noted that she had an occasional cough, which was generally nonproductive but occasionally produced a small amount of white, mucoid sputum. There was no hemoptysis, and the cough, though persistent, did not increase in severity. There was slight tenderness in the right upper quadrant of the abdomen.

In July examination revealed a temperature of 99.9 F., a pulse rate of 86, a respiratory rate of 20 and a blood pressure of 86 systolic and 62 diastolic. The patient was well developed and well nourished and did not appear ill. She was protecting her swollen right wrist. She was alert, cooperative and oriented, but depressed in respect to her illness. There was no local or generalized lymphadenopathy. The sinuses transilluminated well. The teeth were in good condition. The tonsils had been removed. The chest was symmetrical and the expansion good and equal. Breath sounds and the whispered and spoken voice were normally transmitted throughout. No rales were present. The liver, spleen and kidneys were not palpable. Examination of the extremities revealed limitation of motion of the fingers of the left hand because of pain, unaccompanied by local deformity. There were swelling, slight redness and increased local heat, together with pain on motion in the right wrist.

Course and Accessory Examinations.—At the onset of illness, four months previous to our examination of the patient, the agglutination test was performed and no *Brucella* agglutinins were found; an intradermal test with *Brucella* suspension produced erythema together with edema about the size of a 10 cent piece (18 mm.). X-ray examination of the chest disclosed nothing abnormal. A diagnosis of brucellosis was made, and the patient was treated with vaccine for about ten months. Nevertheless the symptoms did not subside. When we made an examination in July, after several months' vaccine treatments, the blood serum gave a positive agglutination reaction with the *Brucella* antigens in dilutions of 1:80. The opsonocytophagic test gave a weakly positive reaction. Intradermal tests with 0.1 cc. of 1:10,000 and 1:2,000 dilutions of brucellergen were negative.

During the fall of 1936 the patient continued to have pain, together with swelling in the joints of the extremities, particularly the wrists and the metaphalangeal joints of the fingers. Finally her left hip became excruciatingly painful. X-ray examinations on four subsequent visits showed increasing peribronchial infiltration with fibrosis, together with a spread of the normal hilar shadow. The x-ray appearances in this case have been reported by Lafferty and Phillips.³¹ A gallbladder series showed a poorly functioning gallbladder without stones.

Serologic studies were made again in October and November. In October the two *Brucella* antigens were agglutinated in dilutions of 1:320 and the opsonocytophagic reaction was strong. In November the agglutinin titer had diminished somewhat and the opsonocytophagic activity was moderate.

Throughout the fall of 1936 the patient continued to have occasional cough, productive of a mucoid sputum which never became purulent or copious. At no time were changes observed in her chest on physical examination. In December 1936 *Brucella suis* was obtained from the blood and from the joint fluid of the right wrist. In March 1937, about three months after completion of this survey, the patient died. Unfortunately there was no postmortem examination.

Epidemiologic Data.—This patient had had no animal contacts. Agglutination tests on twenty-four cows of the herd supplying her with raw milk gave positive reactions for three.

CASE 2.—History and Examination.—E. C., a white woman aged 32, a housewife, referred by Dr. S. W. Davis, when first seen, in August 1936, complained of weakness of three months' duration. The family history was irrelevant. The patient had had fairly good health except for two episodes, to be mentioned presently. However, for many years she had been subject to moderate dysmenorrhea and for the past two years her periods had been rather irregular, with a gradual decrease in the menstrual flow but never a cessation. She regarded herself as always having been an extremely nervous person. About ten years before she experienced several febrile attacks, with weakness. Six years before she had a series of attacks of alternating diarrhea and constipation, accompanied by mucus, without blood or pus in the stools.

In June 1936 the patient noted increasing weakness. The afternoon temperature rose to 99.5 F. or higher on exertion. This elevation of temperature occurred daily except during occasional intervals of two or three days. The patient lost 6 pounds (3 Kg.) in one week because of anorexia. This weight was not regained during her illness. There were occasional night sweats unaccompanied by chills and without offensive odor. In the left arm and over the precordium there was a dull aching with occasional shooting pain. An occasional nonproductive cough was attributed to a postnasal discharge following an attack of allergic rhinitis.

Physical examination disclosed a temperature of 99.2 F., a pulse rate of 85, respiratory rate of 20 and a blood pressure of 110 systolic, 70 diastolic. The patient was rather thin and had a slight pallor. She was alert, intelligent and cooperative. There were no enlarged lymph nodes. The sinuses were clear. The teeth and pharynx were normal. The chest was symmetrical and the expansion good and equal. The heart was not enlarged. There were moderate sinus arrhythmia and a systolic murmur in the pulmonic region. The abdomen was soft; the liver and spleen were not palpable. The extremities were normal.

Course and Accessory Examinations.—The hemoglobin content was 76 per cent; the red blood cells numbered 4,300,000 and the white blood cells 12,200, with polymorphonuclears 78 per cent, lymphocytes 18 per cent, monocytes 3 per cent and basophils 1 per cent. Urinalysis gave negative results. Serologic tests gave a weak opsonocytophagic reaction and positive agglutination reactions with the two *Brucella* antigens in dilutions of 1:40. The intradermal test with brucellergen gave negative results.

The symptoms continued throughout August and September, although repeated physical examinations, including a pelvic examination, showed no abnormalities. X-ray examination of the chest gave normal results throughout the illness. Non-specific shock treatments with injections of lactogen were given at weekly intervals. They were followed by a slight elevation of temperature and malaise lasting a few hours. The lactogen therapy was discontinued after six weeks because there seemed to be no improvement. The patient was then given concentrated liver extract with an initial dose of 3 cc. and succeeding doses of 1 cc. every three weeks for several months. During the liver therapy she showed marked general improvement, as evidenced by the fact that she was afebrile and able to be up all the time and complained only of occasional weakness. Serologic tests made during the recession of symptoms showed a very strong opsonocytophagic reaction and agglutination of the melitensis antigen in a dilution of 1:40.

About November 1 the former symptoms developed, with exhaustion and malaise so severe that she was obliged to return to bed. Depression was marked; afternoon temperatures rose

31. Lafferty, Robert H., and Phillips, Clyde C.: Pulmonary Changes in Patients Suffering from Malta Fever, South. M. J. 30: 595-600, 1937.

to between 99.5 and 100 F. Moderate hypotension was present, the blood pressure being from 98 systolic, 68 diastolic to 84 systolic, 60 diastolic. Repeated physical examinations gave negative results. In December the patient was somewhat improved and started on a regimen of moderate activity. Serologic tests were repeated, and the opsonocytaphagic test was found to be weakly positive; the agglutinin titer remained 1:40. From a guinea pig given an injection of blood in December, a culture of *Brucella melitensis* was obtained.

Epidemiologic Data.—The patient had had no animal contacts. She consumed raw milk from a herd of cows with a history of abortions. Agglutination tests performed on seventy-four cows of this herd gave positive reactions for twenty-one. A herd of goats was kept on the same farm with the cows.

CASE 3.—History and Examination.—W. W., a woman aged 33, a bank employee, referred by Dr. S. W. Davis, when first seen, in July 1936, complained chiefly of fever, weakness and malaise, which had persisted for seven months. The family and the past history were irrelevant.

Prior to Christmas of 1935 the patient had been in good health. At that time there developed an illness characterized by fever, weakness, general aching, exhaustion and dull frontal headache which persisted for two months and was considered to be "flu." About four months later the menstrual flow increased, with occasional passage of clots of blood. The patient had returned to work, however, and felt well until May 1936, when she had an attack identical with the first, lasting two weeks. The maximum temperature during these episodes was 101 F. The symptoms subsided for about a month. She was then forced to go to bed again because of extreme exhaustion. Anorexia and fever developed, together with constipation, insomnia, nervousness, irritability and profound depression. She noted a sensation of suffocation and fear of closed spaces. She lost about 10 pounds (4.5 Kg.) during four weeks of illness. During the interval between attacks she had been afebrile, to the best of her knowledge, but she noted increasing difficulty in doing her work because of weakness, nervousness and irritability. During the second attack an occasional cough productive of a scanty mucoid sputum developed, which persisted throughout the illness.

Physical examination disclosed a temperature of 99.8 F., a pulse rate of 84, a respiratory rate of 20 and a blood pressure of 112 systolic, 68 diastolic. The patient was well developed and well nourished and did not appear ill. There were some small erythematous papules on the right leg and the right side of the back, without associated petechiae or tenderness. The sinuses transilluminated well. The teeth were in good condition. The tonsils had been removed. The thyroid was palpable. The chest was symmetrical and the expansion good and equal. The percussion note was resonant throughout. The breath sounds were normal. The liver and kidneys were not palpable. The spleen was palpable at the costal margin. Pelvic examination gave negative results. The extremities showed no abnormalities.

Course and Accessory Examinations.—The hemoglobin content was 94 per cent; the red blood cells numbered 4,300,000 and the white blood cells 4,850, with 38 per cent polymorphonuclear leukocytes, 6 per cent monocytes and 2 per cent eosinophils. Urinalysis gave negative results. No tubercle bacilli were found in the sputum. The blood serum agglutinated abortus antigen in a 1:10 dilution. The opsonocytaphagic reaction was strong. The intradermal test with brucellergin (1:50,000) gave an area of erythema and induration 3 by 5 cm. X-ray examination of the chest showed scattered bronchopneumonic areas and infiltration throughout the parenchyma of both lungs. X-ray examinations of the chest were repeated on three occasions during the following four months. They showed an increase in the density of the described areas. The x-ray appearances were reported by Lafferty and Phillips.³¹

The patient remained in bed for two months, during which time she continued to have a fever, with weakness and nervousness. She was treated with *Brucella*-immune goat's serum in three doses of 20 cc. each on consecutive days; this was followed by rather severe serum sickness, which persisted for eight days. She then began to improve. All her symptoms disappeared for one month, at the end of which afternoon fever and increasing

exhaustion returned. After this relapse she was given liver extract for three weeks, with an improvement in appetite. At this time, in October, serologic tests were again made. The opsonocytaphagic reaction was strong; the agglutination reactions were positive in the 1:20 dilution. After this the patient again began to improve. Blood cultures in November and December were negative. However, from guinea pigs inoculated Dec. 7, 1936, cultures of *Brucella abortus* were obtained.

Epidemiologic Data.—The patient had had no animal contacts. She had consumed unpasteurized milk from a herd said to have been subject to recurring abortions. The owner of this herd did not permit agglutination tests to be done on his cows.

CASE 4.—History and Examination.—V. S., a white girl aged 11 years, referred by Dr. Van Mathews, when first seen, in August 1936, complained chiefly of weakness, anorexia, nausea, loss of weight and low grade fever of eight-months' duration. The family and past history were irrelevant.

In January 1936 the patient had an attack of "flu," which was characterized by general aching, malaise, a temperature as high as 101 F., anorexia and a cough accompanied by pain in the lower anterior part of the chest. This illness lasted for seven days. The other members of the family experienced a similar illness at the same time, but in their cases there was no recurrence. Three days later the patient had a recurrence of symptoms, which persisted for one week, after which she returned to school again but continued to feel tired, weak and nervous to such a degree that she was often obliged to go home. The symptoms were variable from day to day; for a few days she would feel all right, and then she would have another episode of weakness, anorexia, nervousness and irritability. Her temperature was carefully observed and found to be around 97 F. in the morning, rising to 99.4 F. almost every afternoon. She complained from time to time of dull frontal headache and pain in one knee and one shoulder, although there was no swelling, redness or limitation of motion. She lost almost 20 pounds (9 Kg.). X-ray examination of the chest revealed no enlargement of the mediastinal glands but showed scattered small area of bronchopneumonic infiltration throughout the hilus and parenchyma of the lung, which did not suggest tuberculosis. In May 1936 the patient was placed on a regimen of absolute rest in bed. During the period of rest she showed marked improvement, regaining most of the lost weight and feeling well generally except that she continued to have a low grade fever.

Physical examination revealed a temperature of 99.6 F., a pulse rate of 76, a respiratory rate of 20 and a blood pressure of 88 systolic, 64 diastolic. The patient was well developed and well nourished and did not appear ill. She was alert, oriented and cooperative but sometimes seemed depressed and anxious. There was no localized or generalized lymphadenopathy. The sinuses transilluminated well and equally. The teeth were in good condition. The pharynx was normal. The chest was symmetrical and the expansion good and equal; the percussion note was resonant throughout. Breath sounds and the whispered and spoken voice were normally transmitted. The liver, spleen and kidneys were not palpable. The extremities showed no abnormalities.

Course and Accessory Examinations.—In August and again in December 1936 specific tests to detect *Brucella* infection were performed. On both dates agglutination and opsonocytaphagic reactions were negative. Tests performed with brucellergin (1:10,000) and later with a stronger dilution (1:2,000) were negative; intradermal tests with 0.1 and 1 mg. of tuberculin were negative.

In September the hemoglobin content was 11.5 Gm.; the red blood cells numbered 4,210,000 and the white blood cells 5,500, with polymorphonuclear leukocytes 44 per cent, small lymphocytes 44 per cent, large lymphocytes and monocytes 10 per cent and eosinophils 2 per cent. Repeated urinalyses gave negative results. X-ray examination of the chest in September revealed an increase in the density of the previously described bronchopneumonic areas but no increase in their number.

When the patient remained in bed the only symptoms were depression, anxiety and fever. There was a continuous increase in weight. Physical examinations made at monthly intervals showed only a mild hypotension. Finally, in the latter part

of October, the patient was allowed a regimen of gradually increasing activity. After she had been up for a few days, weakness, dizziness, fatigue, anorexia, nervousness and pallor returned. The patient returned to school in the latter part of November, although she was losing weight and the afternoon temperature rose to 99.5 or 100 F.

Blood cultures were planted in November and again in December. No growth was obtained in broth culture, but a culture of *Brucella melitensis* was obtained from a guinea pig inoculated with blood December 8.

Epidemiologic Data.—The patient had had no animal contacts. The herd which supplied her with raw milk was said to have had a history of recurrent abortions for several years. Agglutination tests performed on ninety-six cows gave positive reactions for twenty-seven.

CASE 5.—History and Examination.—H. D., a white woman aged 34, a housewife, referred by Dr. W. G. Bradford, when first seen, in November 1936, complained of loss of energy of six months' duration. The family and the past history were irrelevant.

The present illness was insidious in its onset, beginning in May 1936, when the patient first noticed loss of energy, accompanied by an elevation of temperature sometimes as high as 101 F., general muscular aching, nervousness and irritability. The headache was dull and usually frontal but occasionally in the occipital region. Anorexia resulted in a loss of 10 pounds (4.5 Kg.) in two months. In August the patient went to the mountains, where her health improved. In November there was a recurrence of the previous symptoms together with dizziness. This attack was so severe that the patient preferred to remain in bed.

Physical examination revealed a temperature of 99.8 F., a pulse rate of 84 and a respiratory rate of 20. The general physical examination gave negative results except to disclose a two and one-half months pregnancy.

Course and Accessory Examinations.—The hemoglobin content was 84 per cent; the red blood cells numbered 4,320,000 and the white blood cells 11,500, with polymorphonuclears 76 per cent and lymphocytes 22 per cent. Urinary examination gave negative results. The opsonocytaphagic reaction was strong. The two *Brucella* antigens were agglutinated in dilutions of 1:20. Intradermal tests with brucellergin in 1:10,000 and 1:2,000 dilutions were negative. From a sample of blood taken in December *Brucella melitensis* was obtained in broth culture. This organism was also obtained from a guinea pig given an injection of the blood.

Recent information was received from the attending physician, who stated that the pregnancy terminated in a normal spontaneous delivery at full term. Since the birth of the child the patient has been well except for one episode of unexplained fever.

Epidemiologic Data.—The patient had had no animal contacts. She received raw milk from the same herd as patient 4.

COMMENT

From the literature and from the cases reported in this paper, a general description of chronic brucellosis may be given as follows: In severity it varies from a very mild form to a prolonged progressive disease which may end fatally, as it did in case 1. Chronic brucellosis may appear as a sequel to an acute attack or the onset may be insidious. The patient may be aware of no illness other than the mild symptoms of weakness, nervousness, exhaustion on slight effort, suffocating sensations, palpitation, insomnia, depression, irritability or a sense of impending disaster. Fever is usually present in low degree; it may be absent for weeks or months, when the patient may suffer from any or all of the mentioned symptoms. A common feature of chronic brucellosis is the lack of abnormalities to be found on physical examination except for occasional splenic enlargement and hypotension. When the mild symptoms described occur in a patient with no apparent

physical abnormalities, the picture resembles that classified as psychoneurosis. One of us¹¹ pointed out in an earlier paper that in many cases of chronic brucellosis a diagnosis of neurasthenia is made. In general, our cases all illustrate the chief feature of chronic brucellosis—weakness, low grade fever and a lack of objective signs of disease.

The occurrence of roentgenologically demonstrable lesions of the chest with chronic brucellosis has been pointed out by Bogart,³² by Beatty³³ and by Lafferty and Phillips,³¹ who studied cases 1, 3 and 4. The appearances are variable, but in general there are an increase in the hilar root shadows and progressive peribronchial infiltration, particularly through the bases. They are similar to pictures seen with other chronic infections of the upper respiratory tract but differ in certain details. We do not maintain that they are pathognomonic of brucellosis but suggest that patients in chronic ill health should be examined for lesions of the chest. Patient 3 was referred to Lafferty and Phillips³¹ with tuberculosis suspected. They found the x-ray picture so similar to that of patient 1, which they had previously studied, that patient 3 was referred to us as possibly having brucellosis. Later, roentgenograms of the chest in case 4 were found to present a similar picture.

In none of the five cases was the agglutinin titer as high as 1:80, which is usually regarded as the minimum of diagnostic significance. (In case 1 the agglutination reaction was negative until after the course of vaccine treatments had begun.) In cases 2 and 3 there was a titer of 1:40, which has some diagnostic significance, as shown in our earlier paper. In case 4 no agglutinins could be demonstrated in the blood in repeated examinations. In case 5 agglutinins could be demonstrated only in low dilution. All five patients had been ill for more than six months when the agglutination tests were performed.

Only patient 3 gave a definitely positive intradermal reaction. Patient 4 gave repeatedly negative opsonocytaphagic reactions; for the four other patients the opsonocytaphagic reactions varied from weak to strong, differing for a given patient in tests repeated at intervals of a month or more. One of our patients died after having shown a very strong opsonocytaphagic reaction. Thus the five patients proved by culture to be infected with *Brucella* demonstrate the unreliability of the specific tests to detect chronic brucellosis, and they demonstrate that erroneous conclusions may be drawn if a strong opsonocytaphagic reaction is interpreted as a sign of immunity.

Among the twenty-two patients in Charlotte for whom a diagnosis of chronic brucellosis was made, seven were children. The agglutination reaction was negative for all of these, thus agreeing with the observation of Huddleson and his collaborators.¹² In two cases a positive intradermal reaction was the only indication of *Brucella* infection; in one case both the intradermal and the opsonocytaphagic reactions were positive; in four cases (including case 4), none of the specific reactions were positive. In case 4 *Brucella melitensis* was cultivated from the blood. These results suggest that children may be more susceptible to *Brucella* infection than is generally suspected and that the disease may fail to be recognized in children because

32. Bogart, F. B.: Pulmonary Changes in Undulant Fever, South. M. J. 29: 1-9, 1936.

33. Beatty, Oren A.: Manifestations of Undulant Fever in the Respiratory Tract, Am. Rev. Tuberc. 36: 283-289, 1937.

it occurs in a mild obscure form without the development of agglutinins.

The advantage of clinical considerations, as compared with laboratory tests for the detection of chronic brucellosis, may be illustrated by comparing the results of this study with those of Gould and Huddleson,³⁴ who used intradermal hypersensitivity to brucellergin and opsonocytaphagic reactions as bases for finding *Brucella*-infected subjects. From among 845 subjects considered to be infected with *Brucella* on the basis of specific tests, they succeeded in cultivating the organism in blood obtained from four. Among thirteen of our patients carefully selected as probably having brucellosis on an exclusively clinical basis, Poston²⁹ obtained *Brucella* from five. Failure to obtain the organism does not preclude the possibility of brucellosis.

In the cases presented in this paper there were no known direct contacts with infected animals. Apparently indirect contact by means of the consumption of raw infected milk or other dairy products was the only exposure to infection.

SUMMARY

Twenty-two cases in which chronic brucellosis appeared to be the logical diagnosis were found during a six months survey of Charlotte, N. C., a city of about 107,000 inhabitants.

There was no history of direct contact with infected animals in any of five cases in which the causal organism was obtained. Apparently infection was contracted through the ingestion of infected dairy products.

WESTERN EQUINE ENCEPHALOMYELITIS IN A LABORATORY WORKER

L. D. FOTHERGILL, M.D.
MARGARET HOLDEN, PH.D.
AND
R. W. G. WYCKOFF, PH.D.
PEARL RIVER, N. Y.

For a number of years, work was carried on with the viruses of equine encephalomyelitis on the assumption that these diseases were not communicable to man. Last summer, however, at least forty human cases of encephalitis appeared in New England during an epidemic of equine encephalomyelitis; virus was recovered from several of the patients and was shown to be that of Eastern encephalomyelitis by Fothergill, Dingle, Farber and Connerly¹ and by Webster and Wright.² Howitt³ also has reported from California a fatal human case of Western encephalomyelitis and has shown that the blood of several individuals there with a previous history of encephalitis had neutralizing antibodies against Western virus. Reports have reached us of several cases of encephalitis among farmers during last year's equine epidemic; it is not improbable that some of these were due to the Western virus.

We report here the circumstances surrounding the death of a laboratory worker who was infected with the Western virus with which she had been working. R. R., a woman aged about 30, took employment at the Lederle Laboratories Feb. 24, 1939. Ten days later she complained of a headache which continued through the next day, March 6. By the 8th she was confined to her home with what was at first thought to be influenza. She had a continuing fever, which reached 104 F. by the 11th and was followed by convulsions, coma and death on the night of the 12th. Blood and spinal fluid were taken on the 11th. When injected intracerebrally the spinal fluid produced a paralysis and death in young mice and guinea pigs; blood did not produce disease. Portions of the fore and hind brain, taken at autopsy, were studied independently by three groups of observers.

Each isolated virus and by typing has found it to be that of Western equine encephalomyelitis. In one set of experiments it was established that standard Western immune horse serum neutralized the patient's virus (after one mouse passage), whereas no comparable neutralization was brought about by either normal or Eastern immune horse serum or by normal human serum. In these tests the virus and serum were incubated together for one and one-half hours and the mixture injected intracerebrally into 3 weeks old mice. In the experiments of the second group it was shown that the patient's virus produced a fatal encephalitis when injected intracerebrally into rabbits, guinea pigs and mice; it was also observed that mice hyperimmune to herpes, B, rabies, St. Louis and Eastern equine encephalomyelitis viruses were as susceptible as normal mice to the patient's virus. In this second set of experiments the virus was identified as Western by specific neutralization tests following Olitzky's⁴ technic wherein virus-serum mixtures are injected intraperitoneally into 12 to 16 day old mice. It was found that immune Western serum protected mice in all dilutions with a titer of at least 10^7 whereas no neutralization was brought about by either normal or Eastern immune serum. The third identification was obtained by inoculating Western immunized, Eastern immunized and normal guinea pigs with the human virus (after one guinea pig passage); all the controls and all the Eastern immune pigs died promptly, while all the Western immune animals remained healthy.

Heart blood was also taken at autopsy. It is interesting that this blood was nearly as rich in antibodies as was a commercial Western immune horse serum.

The mode of infection could not be established. In spite of a system which called for reporting the slightest accident, the patient did not record one; and she did not tell her immediate relatives of any. There were rumors that she injected virus into a finger, presumably by breaking off the soft, curved gold point of the needle being used. Nevertheless a satisfactory confirmation of this has not been possible, and no broken needle was turned in.

This patient is the only one of more than a hundred persons working with encephalomyelitis viruses at the Lederle Laboratories who has shown any clinical symptoms of infection. Several of these people have been for years in intimate contact with the viruses, while a considerable number have worked with them for fifteen months. The personal history of the patient suggests the possibility of an unusual susceptibility. Her mother died about fifteen years ago of an obscure and

apparently unclassified encephalitis. She herself had had a severe tuberculous involvement of the spine. At autopsy, besides the expected picture of encephalitis, Dr. W. R. Strutton found congestion of the lungs, liver and spleen and a large cystic cavity of the right side of the brain, cortex and basal nuclei showed areas of marked perivascular infiltration; the right kidney was tuberculous.

Clinical Notes, Suggestions and New Instruments

LATE MARGINAL ULCER

JEROME SELINGER, M.D., NEW YORK

A man was operated on for a perforated marginal ulcer April 11, 1938, almost exactly twenty-nine years after a gastro-enterostomy had been done for a duodenal ulcer. As far as I have been able to ascertain, this is the longest interval between operation for a duodenal ulcer and the occurrence of a marginal ulcer.

The patient's record was secured from St. Vincent's Hospital in New York, where he was operated on April 29 and discharged May 23, 1909. At that time, under gas and ether anesthesia through a 3 inch incision, a typical posterior gastro-enterostomy was done. The history previous to that operation had extended over a period of two and one half years, the symptoms being marked by pain and vomiting and the vomitus being generally brownish and occasionally streaked with blood. He had put himself on a diet which gave him some relief but not complete relief. He had lost about 30 pounds (13.6 Kg.).

The patient had been in very good condition most of the time since his original operation. The situation was complicated by the fact that he had a bilateral inguinal hernia; that on the right side, being of a scrotal nature, descended frequently, perhaps becoming partially incarcerated. On these occasions he complained of considerable pain throughout the abdomen, and it is perfectly possible that he confused the pain of the recurring ulcer with that of a troublesome scrotal hernia.

On the morning of April 11, 1938, the patient complained of acute pain in the right inguinal region which became progressively worse. He did not secure the usual relief by removing his truss. The hernia was in the scrotum and he was not able to reduce it. There was no nausea or vomiting. I reduced the hernia about 2 p. m. and he reported instant relief. The abdomen did not appear tender, although a complete examination was not made at this time. He felt quite comfortable for a while. The pain later increased and seemed to be higher up in the abdomen. He was seen by an associate of mine, who made the diagnosis of an acute abdominal condition and advised his entering the hospital. When I saw him at 8:30 p. m. at the New York Post-Graduate Hospital he had all the signs and symptoms of an acute perforated viscus, and a diagnosis of perforated marginal ulcer was made. I operated on him at 9:30. Free gastric contents were found in the abdomen. The entire duodenum and part of the jejunum were greatly enlarged and edematous. The old gastro-enterostomy was completely free of adhesions to the surrounding structures. There was a perforation about the size of a green pea at the anastomotic site posteriorly and at the efferent end of the loop. The opening was sutured with three purse-string sutures of chromic catgut; two cigaret drains were inserted and the abdomen was closed in layers.

The patient had a stormy convalescence, for a variety of reasons: (1) his distinct aversion to an operation, he having stated on several occasions that he would prefer to die rather than have an operation; (2) the development of bronchopneumonia; (3) the myocardial abnormalities; (4) the development of a severe psychosis, and (5) overtreatment with drugs.

He got out of bed on several occasions but in spite of everything he made progress, and on the twelfth postoperative day all sutures were removed, at 9:30 a. m. At 2 p. m. it was noted that his dressing had a pink stain. The resident removed

the dressing and found that there was complete dehiscence of the wound. He packed it with iodoform gauze, restrapped it with adhesive plaster and notified my office. I was out of town but an associate who was in the hospital resutured the wound at 5 p. m. Under procaine hydrochloride anesthesia, three through and through silk sutures were introduced and the fascia and peritoneum were sutured with 00 catgut.

The patient's behavior continued about as before. There was no improvement in the psychosis. He was out of bed two or three times within twenty-four hours after the wound had been resutured. He was under the medical care of an associate, who was able to keep him relatively quiet with paraldehyde. Physically he seemed to be better; on the twenty-sixth day we decided to send him home in an ambulance on the theory that being at home and away from the hospital, which he disliked, might hasten his recovery. He was accordingly sent home with a temperature of 100 F. and a pulse that ranged between 90 and 100. A letter was written to his local physician telling him all the facts and urging him to leave the sutures in place at least fourteen days.

He apparently did very well at home. His mental condition cleared; he was gradually allowed out of bed, and on June 29, two and one half months after the original operation, he came into my office, rather shaky but able to get about. On examining his wound I found that the skin had grown under and had refused to unite; he was readmitted to the hospital July 5 for a revision of the wound. The abdomen was reopened, the peritoneum secured, the fascia separated from the skin and firmly sutured with chromic catgut and the skin sutured with silk. On this occasion we kept him in the hospital seventeen days. There was a slight discharge from the wound but it closed promptly and apparently at the present time he is in good condition.

He was seen and presented to the surgical staff meeting at the New York Post-Graduate Hospital Jan. 3, 1939, at which time he was in excellent condition. He had gained 15 pounds (6.8 Kg.), his abdomen was strong and there was no evidence of herniation. He is on a moderately restricted diet.

CEREBELLAR TUMOR WITH ACUTE RESPIRATORY PARALYSIS

REMOVAL OF TUMOR AND RECOVERY

D. H. WERDEN, M.D., SAN DIEGO, CALIF.

Acute respiratory failure followed by removal of a brain tumor, survival and recovery is sufficiently unusual to justify reporting. The case emphasizes the fact that relief of increased intracranial pressure associated with brain tumor may become an acute emergency measure, illustrates the value of ventricular puncture and drainage, and shows that respiratory failure, though usually fatal, does not necessarily indicate an altogether hopeless prognosis.

REPORT OF CASE

History.—Jean D., a girl aged 14 years, was seen in neurosurgical consultation for Dr. Ernest Thelen April 16, 1937, approximately five minutes after the patient had ceased breathing. The only information available at that time was that the patient had been ill for about three months with loss of weight, headache and failing vision. She had been under treatment for intestinal influenza and the day before (April 15) had been admitted to San Diego County Hospital under the provisional diagnosis of tuberculous meningitis.

Examination.—A hasty superficial examination revealed that the patient was dehydrated, extremely emaciated and in deep coma with dilated fixed pupils. The pulse rate was 60 and the patient was breathing only by artificial respiration given by Dr. Clark, an intern. All the extremities were flaccid. The disks were blurred and elevated about 2 diopters, with some pallor, suggesting secondary optic atrophy. The spinal fluid examined the day before had contained no cells and no fibrin pellicle. The blood count was red cells 4,570,000, white cells 16,150, hemoglobin 91 per cent and polymorphonuclear leukocytes 92 per cent. No other diagnostic studies had been done.

On the basis of a history of pressure symptoms without localizing symptoms, the negative spinal fluid cell count and the sudden respiratory failure, a presumptive diagnosis of cerebellar tumor was made.

Operation.—Ventricular Drainage: The patient was immediately sent to the operating room, where artificial respiration was continued by forced inhalation of a mixture of carbon dioxide and oxygen alternated with manual compression of the lungs. Without an anesthetic, preparation of the head or sterilization of the instruments, a left posterior parietal trephine was made and the ventricle tapped and slowly drained of about 60 cc. of ventricular fluid over a period of forty minutes. At the end of this time spontaneous breathing ensued but was supplemented by carbon dioxide and oxygen.

At noon, three hours after operation, the patient was still breathing but the pulse rate had increased to 168. A transfusion of 450 cc. of citrated blood was given. By 3 o'clock the pulse rate was 120; respiration was more quiet and deep. The patient was still in deep coma. On the assumption that her condition was about as good as it ever would be, suboccipital exploration was decided on.

Suboccipital Exploration: With procaine hydrochloride locally, a curved linear incision was made 2 cm. above the supranuchal line from one mastoid process to the other. After the galea had been incised the scalp was reflected downward for about 2 cm. The deep cervical fascia was then severed about 1 cm. from its attachment at the nuchal line and it, together with the subjacent muscles of the neck and periosteum, was elevated from the occipital bone down to the foramen magnum. A trephine was made in each side of the occipital bone and the entire occipital bone rongeuired away up to the lateral sinus and down to and including the posterior half of the foramen magnum.

Before the dura was opened the ventricle was again tapped, about 80 cc. of fluid being drained off. The dura was then opened and the cerebellar hemispheres were palpated. A midline incision was made in the vermis to a depth of about 1 cm. At this point a reddish mass was encountered which proved to be a blood clot. This was removed, revealing a round encapsulated tumor. The surrounding cerebellar tissue was retracted gently with cotton pledgets and retractors. With a small periosteal elevator the tumor was lifted from its bed and removed in toto. The cavity was irrigated with saline solution and lightly packed with cotton for a few minutes until the hemorrhage was controlled. After a few minutes the cotton packs were removed and the cavity was further irrigated. The dura was left open; the deep cervical muscles and fascia were sutured to the fascial attachment at the supranuchal line with interrupted silk sutures and the skin likewise. No drains were used.

Conditions Found at Operation: The dura covering the cerebellar hemispheres was under tremendously increased tension; the ventricular fluid was under increased tension despite the fact that drainage had been done approximately six hours before. After drainage of about 80 cc. the tension on the cerebellar hemispheres was reduced to approximately normal. When the dura was reflected neither hemisphere seemed to be abnormally enlarged and no mass could be felt by palpation. The vermis, however, did appear slightly more bulging and more widened than normal, and both cerebellar hemispheres and the lower tip of the vermis were herniated into the foramen magnum. No cisternal fluid was present. When a ventricle needle was passed into the left cerebellar hemisphere a resistance was felt which gave the impression that the ventricle needle was passing over the edge of a firm mass. After the needle was withdrawn, considerable blood oozed from the puncture wound.

The vermis was incised and a reddish mass was encountered which at first was thought to be a tumor but later proved to be a blood clot, measuring in thickness about 0.5 cm. and found to be surrounding the posterior half of a tumor. The tumor was also partially surrounded by yellow cystic fluid to at least two thirds or three fourths of its circumference. This fluid, together with the hemorrhage, had separated the tumor from the cerebellar tissue in almost its entire circumference.

The tumor itself was about the size and shape of a small walnut but was smooth and entirely encapsulated and could be

shelled out with very little difficulty. A moderate amount of bleeding followed but was easily controlled. Owing to the rather deep position of the tumor bed, the base of the cavity was not palpated. The entirely encapsulated appearance of the tumor gave one the impression that there were no other adjacent nodular masses. Following removal of the tumor, the tension was apparently not increased.

The pathologic report by Dr. H. A. Ball was as follows: The specimen consisted of the brain tumor, which was 3.5 by 1.5 cm., a small amount of brain tissue and three or four blood clots. The microscopic appearance was that of an astroblastoma.

At 7:20 p. m. 500 cc. of citrated blood was given by venesection. The operation was finished at 7:55 and the patient was returned to bed with a pulse rate of 104 and was breathing spontaneously at about 32 respirations a minute.

Postoperative Course.—This was extremely stormy. The patient remained in coma for thirty-two days. On the first postoperative day the temperature rose to 105.6 F. rectally; on the fifth day there was cyanosis and the pulse rate was 160 a minute; on the fifteenth day the patient became noisy and moved the upper extremities for the first time. She continued to be involuntary, irrational, cried excessively and had difficulty in chewing but would occasionally respond to commands. On the thirty-second day the patient was conscious for the first time and began turning herself in bed without help. She could not speak but would shake or nod her head to indicate "no" or "yes." Involuntary crying and frequent vomiting of breakfast continued. Urticaria developed on the forty-sixth day with a pulse of 144 but was relieved by small doses of epinephrine. On the fifty-first day the patient called "mama," the first word she had said since the day of operation. Five days later she asked for watermelon and milk. Speech was characteristically bulbar. The patient was sent home by ambulance on the fifty-seventh day.

Other conditions of interest during this time were the following: The temperature was up to 103 F. until the ninth day and 102 F. until the sixteenth day. Ventricular drainage was done repeatedly without moving the patient from her room; the exact number of times was lost count of. Contractures of the hamstring muscles could not be prevented. Body weight and texture and color of the skin were actually improved, even during the thirty-two days of coma, by nasal tube feeding.

On discharge the wound was healed but the decompression area was under some pressure. There was marked incoordination of ocular movements and total blindness with optic atrophy, which was undistinguishable from a primary type of optic atrophy. All deep reflexes were absent; abdominal reflexes were absent and the Babinski signs were not present. Cerebration was slow, but the patient's replies were accurate and intelligent.

For several months at home the patient remained in bed. The drawing speech slowly improved. She was bright, jovial, intelligent and emotionally stable. After four months she was returned to the hospital. There had been some morning vomiting. Treatment with 2,000 roentgens was given through two fields by Dr. John Kellogg.

At present the patient is normal mentally. Speech is normal. Blindness, pupillary fixation to light and optic atrophy are complete. Contractures are partially overcome and walking is possible with support. The patient is otherwise subjectively and objectively well.

SUMMARY

The preoperative diagnosis in this case of cerebellar tumor was made in haste and on scanty but sufficient evidence. Respiratory paralysis lasted approximately forty minutes and was relieved by expedient ventricular drainage and artificial respiration. Successful complete removal of a cerebellar astroblastoma resulted in cure to date (one and one-half years). At present optic atrophy, blindness and some disability in walking are the only residual conditions.

COMMENT

Acute respiratory failure is a frequent cause of death in patients with unoperated cerebellar tumors. Even the early signs of impending medullary failure carry an extremely poor prognosis unless immediate relief of intracranial pressure is obtained. In the case herein reported, the patient has survived

not only prolonged complete respiratory paralysis but also removal of the tumor.

Cerebral anoxia during apnea undoubtedly contributed to the prolonged unconsciousness and stormy postoperative course but did not result in subsequent mental impairment. The same process, however, was sufficient to result in blindness when superimposed on an already existing papilledema and secondary optic atrophy.

CONCLUSIONS

1. The advantage of early diagnosis is obvious.
2. Delayed diagnosis permits just such an emergency as that cited to occur, in which event immediate ventricular drainage is imperative.
3. The axiom "where there is life there is hope" is applicable in certain cases of brain tumor even after breathing has ceased and "life" is limited to cardiac function.

Special Clinical Article

STRICTURES AND INJURIES OF BILE DUCTS

A STUDY OF RESULTS OF OPERATIONS IN
EIGHTY CASES

CLINICAL LECTURE AT ST. LOUIS SESSION

WALTMAN WALTERS, M.D., Sc.D.

ROCHESTER, MINN.

This study of benign strictures of the common and hepatic bile ducts is based on eighty consecutive cases in which I have performed operations at the Mayo Clinic during the past fifteen years. The follow-up study of these cases has been carried out by Dr. Everett B. Lewis,¹ my first assistant. One of my former first assistants, Dr. K. K. Nygaard (now of Oslo, Norway), and Dr. Shelden and I summarized the results of fifty-one of these cases in 1937.²

There were ten deaths in the series of eighty cases, a mortality of 12.5 per cent (table 1). In but twelve of the cases (15 per cent) was the stricture localized and small enough so that it could be excised and the ends of the common bile duct anastomosed together. Fifty-eight per cent of these patients have been well since their operation (table 2), three have been well for more than five years, and one for more than three years. When the lower portion of the common bile duct was strictured, there was sufficient common or hepatic duct above the stricture to allow an anastomosis of it to an opening made in the duodenum in 61 per cent of the cases (choledochoduodenostomy and hepaticoduodenostomy); 68 per cent of these patients have been well since the operation (fig. 1). In eight of these more than five years has elapsed since the operation, and in eight more than three years. There was a mortality of 6 per cent in the group of cases in which choledochoduodenostomy or hepaticoduodenostomy could be performed (table 3). The cause of death in

the three cases in which this operation was performed was hepatic insufficiency. In fifteen cases the extrahepatic ducts were strictured throughout their entire length, it being necessary to establish external biliary fistulas, some of which fistulas were transplanted into the stomach or duodenum.

This summary of the types of operation and the results obtained will serve to establish the fact that, generally speaking, there are three types of operations which can be performed in the surgical treatment of stricture of the common and hepatic bile ducts, the choice of operation being determined by the extent of the stricture and the amount of uninvolved portion or portions of

Fig. 1.—First step in performing choledochoduodenostomy. An outer row of silk sutures has been introduced approximating the common bile duct, above the site of its stricture, and the duodenum. A transverse incision has been made in the common bile duct and opposite it a longitudinal one has been made on the anterior wall of the duodenum.

the common and hepatic bile ducts. It is further illustrative of the fact that the surgical treatment of stricture of the common bile duct is far from being hopeless; for, if sufficient duct remains adjacent to or above the site of stricture to allow an anastomosis between the ends of the duct or an anastomosis of the duct above the stricture with an opening which one makes in the duodenum, thereby obtaining an accurate mucous membrane to mucous membrane anastomosis, 58 and 68 per cent of the patients, respectively, have what might be termed excellent results without evidence of recurring biliary obstruction. Furthermore, in that most serious group of cases in which the extrahepatic bile ducts are completely strictured, surprisingly good results have been obtained in a few cases by establishing an external biliary fistula and by transplanting the latter into the stomach or duodenum or by suturing a small opening made in the duodenum to the hilus of the liver around the biliary sinus in which a rubber tube has been inserted into the intrahepatic duct (fig. 2). In two

2. Nygaard, K. K.; Shelden, C. H., and Walters, Waltman: Strictures of the Bile Ducts: Results in Fifty-One Operative Cases, *Proc. Staff Meet., Mayo Clin.* 12: 25-30 (Jan. 13) 1937. Walters, Waltman: Resections of the Common and Hepatic Bile Ducts and Ampulla of Vater for Obstructing Lesions: Results in Thirty Cases, *Surg., Gynec. & Obst.* 56: 235-241 (Feb.) 1933.

cases in which an extrahepatic bile duct was not present and drainage of the intrahepatic duct was established by catheter, spontaneous fistulas developed between the sinus created by the catheter and an opening in the duodenum, apparently the result of necrosis from the constant pressure of the catheter (fig. 3). In both cases, complete relief of biliary obstruction was obtained with free entrance of bile into the gastrointestinal tract.

In spite of these encouraging results the seriousness of stricture of the common and hepatic bile ducts should not be minimized. The discouraging part of the problem is that 10 per cent of the patients who had choledochoduodenostomy or hepaticoduodenostomy performed had recurring episodes of biliary obstruction after returning home, and 16 per cent died at home over varying periods because of hepatic insufficiency and hemorrhage (table 1). Even in the group of cases in which the stricture was small enough to excise, making an end to end anastomosis of the duct or a plastic enlargement of the point of narrowing, 8.3 per cent of the patients had recurring episodes of biliary obstruction

ducts may produce a postoperative stricture of the common or hepatic bile ducts. I recall one case in particular in which, at the time of the patient's appearance at the clinic, an external biliary fistula was present. At operation on March 30, 1936, I found and removed a round calculus about 1.5 to 1.75 cm. in diameter from the ampulla, where it was firmly fixed and probably had been present for sufficient time to produce pressure necrosis of the mucous membrane of the ampullary portion of the common bile duct, for, subsequent to the removal of the stone and healing of the fistula, evidence of recurring obstruction occurred for which a choledochoduodenostomy was performed on Nov. 30, 1936. Multiple small stones, 8 mm. in diameter, were also removed from the common and hepatic ducts at this time.

Although this patient made a good recovery and was well for several months, attacks of pain without jaundice recurred. I operated on her a second time on Jan. 26, 1939, finding the common and hepatic bile ducts filled with small stones from 2 to 10 mm. in diameter with

TABLE 1.—Results of Eighty Operations Performed for Stricture of the Common Bile Duct

Establishment of external biliary fistulas	8	2 (both spontaneous biliary fistula to duodenum)	2	1	1, hemorrhage	3	Hepatic insufficiency
Total.....	80	45 (56%)	10 (12.5%)	15 (19%)		10 (12.5%)	

after returning home and 25 per cent died later at home from hepatic insufficiency (table 2).

Furthermore, even though the hospital mortality rate in the series of eighty cases was but 12.5 per cent, it must not be forgotten that an additional 19 per cent of the patients in the series died at home, the cause of death being hepatic insufficiency with and without hemorrhage, complicated by pneumonia in two cases.

In giving the gloomy side of the picture, I am merely emphasizing the seriousness of the surgical condition in the hope that, as a result, its incidence will occur less frequently; for, in seventy-seven of the eighty cases, the stricture occurred after operations on the gallbladder or bile ducts. The three cases in which operative procedures on the bile ducts could not have been an etiologic factor, respectively, consisted of a neurofibroma at the junction of the hepatic and common ducts, a calcified pancreatic cyst that compressed the common bile duct, and an inflammatory stricture. That some of the cases probably were not due to injury of the ducts is evidenced by the fact that, according to the history, a cholecystostomy was performed in five cases, or 6 per cent. I would call attention also to the fact that, in this study of stricture of the common duct, cases of malignant stricture have been excluded. In other words, causes other than operative injury of the bile

considerable narrowing of the stoma previously made in the course of performing choledochoduodenostomy. The stones were removed and an anastomosis was again made and has been followed by a good result. The case is important because it illustrates that if a stone becomes impacted in the common bile duct there may occur narrowing of the duct sufficient to produce

TABLE 2.—Plastic Reconstruction of Bile Ducts in Twelve of Eighty Cases of Stricture of the Common Bile Duct

biliary obstruction; the same thing may occur after a satisfactorily performed choledochoduodenostomy. In addition, when choledochoduodenostomy or hepaticoduodenostomy has been performed and symptoms of recurring obstruction take place, the patient should be given the benefit of exploration of the biliary tract, because in some of these cases stones may be found

in the ducts above the anastomosis which may be narrowed down sufficiently to be one of the causes of the development of the common duct stones. Not only can the stones be removed but also the anastomosis may be enlarged or a new or additional anastomosis may be made, if necessary.

I wish to emphasize, therefore, the value of exploration of the biliary tract in all cases in which there is evidence of biliary obstruction, no matter what the history, when viewed in the light of previous operative observations or reported operative procedures, seems to indicate as to the cause or the possibility of relief of the recurring biliary obstruction. I have in mind a woman aged 27 whose surgeon had found at operation a very severely infected, gangrenous gallbladder which was removed without difficulty, a catheter being inserted into the common duct through the cystic duct. With removal of the catheter a biliary fistula developed and at operation the surgeon was under the impression that he had anastomosed both hepatic ducts to the stomach. Because of the shortness of the hepatic ducts, what would seem to be an almost insurmountable problem in technic presented itself when the young woman began to show signs of recurring biliary obstruction. Because of her youth and her very good general condition it was decided to operate again and explore the ducts. At operation a dilated common bile duct, about 1.4 cm. in diameter and of about the same length, was found above the stricture so that an accurate anastomosis could be made between it and an opening made in the duodenum. This procedure has been followed by a good result.

A third case in which operation was performed several years ago further emphasizes the value of exploring the biliary tract when there is evidence of biliary obstruction with fistula. This patient, a Central American, presented himself at the clinic with a letter from his surgeon, who suggested that the external biliary fistula which was present be transplanted into the patient's stomach or duodenum. As there was some uncertainty as to what part of the biliary tract the fistula communicated with, it was thought best to explore the biliary tract through an incision made on the median side of the fistula, allowing the latter to remain attached to the liver so that it could be used for transplantation into the stomach or duodenum, if necessary. The fistulous tract was found to communicate with an enlarged stump of the hepatic duct of sufficient length and diameter to enable one to make an accurate anastomosis between the duct and an opening made in the duodenum. The results of such an operation, as a rule, are far superior to transplantation of a biliary fistula.

Exploration of the interior of the duct with the scoop, which should always be done before any plastic procedure is attempted, brought out three stones, the largest one being about 1 cm. in diameter. Failure to recognize these stones in all probability would have resulted in recurring episodes of biliary obstruction, leading to the erroneous assumption that the passage at the site of the biliary-intestinal anastomosis had become contracted.

REDUCTION OF THE INCIDENCE OF STRICTURE

Although every surgeon of experience may injure a common bile duct, I believe that it is fair to state that the incidence of stricture of the common bile duct will decrease as the surgeon's experience in the management of lesions of the biliary tract increases. The remarkable thing to me is the relative infrequency with which the condition develops when one considers the extensive

Fig. 2.—Anastomosis between the intrahepatic bile ducts and the duodenum; a, scar showing stricture of entire length of extrahepatic biliary tree; b, a portion of a catheter has been inserted into the intrahepatic duct; c, the edges of an incision in the anterior wall of the duodenum have been sutured to the liver around the intrahepatic portion of the catheter; d, completed operation showing immobilization of the duodenum around the anastomosis by sutures between the duodenum and the liver.

nature of infections which occur in and around the gallbladder and bile ducts as the result of acute obstructions occurring to these structures, usually as the result of delay in the surgical treatment of gallbladder disease. I have seen cases in which at first glance an enlarged common bile duct adherent to a contracted gallbladder gave evidence of being part of the gallbladder itself. In other cases of acute, subacute and chronic disease of the wall of the gallbladder I have spent considerable time and care in dissecting an adherent gallbladder from the hepatic duct. In a few cases in which the mechanical difficulties of the operation were accentuated because of the size of the patient or the disturbed anatomic relationships as a result of infection, the cystic artery has been difficult to ligate accurately and a hemostat has been left on, rather than take a chance of tearing the cystic artery so close to

the hepatic artery that it would be necessary to ligate or clamp the hepatic artery or injure the common duct by hemostat or ligature.

The corollary of this seems to be that under such difficult conditions the wise surgeon of average experience is going to be satisfied in many of the most difficult cases with the performance of a cholecystostomy rather than attempt to do a cholecystectomy. Seventy-eight per cent of the strictures in this series occurred after cholecystectomy alone, and in an additional 11 per cent it occurred after cholecystectomy and choledochostomy, a total of 89 per cent in contrast to

ampulla of Vater masked by the edematous head of the pancreas. In such a case the gallbladder can be used to restore biliary-intestinal continuity if the pancreatic or biliary obstruction occurs.

As an example, a man aged 67 came to the clinic on May 27, 1936. There was a large tumor in the right upper quadrant which he had first noticed in 1929. He did not have symptoms referable to the tumor other than belching and gas, which had been present for thirty years. Diagnoses of a cyst of the pancreas and cholecystitis with stones were made. A large calcified cyst in the head of the pancreas was producing sui-

TABLE 3.—Choledochoduodenostomy and Hepaticoduodenostomy in Forty-Nine of the Eighty Cases of Stricture of the Common Bile Ducts

7.5 per cent occurring after cholecystostomy. I appreciate the fact that there has been a tendency to relegate cholecystostomy to the background because of a reported incidence of recurring cholecystitis all the way from 25 to 50 per cent or more. My own experience now over a period of fifteen years would indicate that in selected cases cholecystostomy may be the operation of choice and also that it is followed, under

sufficient pressure against the pancreatic portion of the common bile duct to cause some question as to whether or not a biliary fistula would develop after the removal of the diseased gallbladder, which contained stones. For that reason, on Nov. 9, 1936, a cholecystostomy was performed rather than a cholecystectomy, after first incising and draining the multiple pancreatic cysts on June 18. Bile continued to be discharged through the cholecystostomy sinus and it was necessary to perform a cholecystogastrostomy four and a half months later, on March 29, 1937. This has been followed by complete subsidence of symptoms and satisfactory passage of bile into the gastrointestinal tract. The patient wrote in December 1938 that he was working all the time and was feeling very well.

It has been my experience that if, after cholecystostomy, cholecystectomy becomes necessary, it can usually be done with greater ease and certainly with much greater safety to the patient because of the absence of jaundice and the lessened likelihood of bleeding. For the patient whose previous operation was done for acute or subacute inflammation of the gallbladder, there is less likelihood too of injury of the common bile duct because of the subsidence of the acute inflammatory process, unless the latter has recurred. The other point which I think is of the utmost importance is that, if one does injure the common bile duct at the time of operation, such an injury should be recognized and should be repaired or reconstruction done immediately. The technic of such a procedure then is much easier and safer than at a later time when infection of the liver or wall of the duct has resulted during the progressive occlusion of the bile duct by the stricture.

PREPARATION OF THE PATIENT AND TECHNIC

A few comments on surgical management may not be amiss. Certainly the patient with stricture of the common duct must be adequately prepared for operation in order to improve the function of the liver and to prevent bleeding. In this connection the importance of administration of dextrose and the use of vitamin K

Fig. 3.—X-ray appearance of stomach and duodenum: the duodenal fistula communicates with the biliary fistula within the abdomen.

such circumstances, by surprisingly good results with a low operative risk and an incidence of recurring inflammation or gallstones not to exceed from 15 to 20 per cent. This applies particularly to patients who have obstructive jaundice and have common duct stones and gallbladders the walls of which may have lost some of their elasticity as a result of recurring inflammation. It also applies to jaundiced patients who do not have common duct stones but have an associated pancreatitis and cholangitis or an unsuspected small tumor of the

and bile salts³ cannot be overemphasized. An elevated prothrombin time as an indication for such therapy before and after operation in our experience has furnished an accurate indication of the tendency to bleed.

At operation, if one uses sharp dissection close to the liver usually no difficulty is encountered in finding the hepaticoduodenal ligament. An aspirating needle or syringe will help one find the stump of the common or hepatic duct and will help to prevent mistaking the portal vein for the common bile duct.

One point in particular should be repeatedly emphasized and that is never to give up hope of finding enough duct above the stricture to allow a direct anastomosis of it to the duodenum. Time and again I have thought the entire extrahepatic biliary tree to be strictured but have found on dissecting close to the liver and higher and higher into its hilus that usually there is a fringe of duct of sufficient length to permit its anastomosis with the duodenum. If such is not the case, the hilus of the liver should be needled with an aspirating needle and syringe until the dilated intrahepatic duct has been tapped. Then, leaving the needle in and using it as a guide, one can make an opening into the intrahepatic duct and insert a catheter, allowing it to remain until the jaundice has subsided and hepatic function has improved to permit a reconstructive biliary-intestinal anastomosis. Or a piece of catheter can be inserted with one end in the hepatic duct and the other passing through an opening made in the duodenum, and the edges of the opening are sutured to the liver adjacent to the catheter (fig. 2).

SUMMARY

A study of eighty consecutive cases of stricture of the common bile duct in which surgical procedures have been performed at the Mayo Clinic by the author forms the basis of an evaluation of the types of operation performed.

In forty-nine, or 61 per cent, of the cases, choledochoduodenostomy or hepaticoduodenostomy was performed with a hospital mortality of 6 per cent. Thirty-three, or 68 per cent, of these patients have been well without evidence of recurring obstruction, eight for more than five years and eight for more than three years.

In twelve of the cases, or 15 per cent, plastic operations have been performed on the duct, consisting of excision of the stricture with anastomosis of the ends of the duct and, in a few cases, plastic enlargement of the narrowed or strictured portion of the duct, usually with partial excision of the strictured portion. Seven, or 58 per cent, of these patients have been free from evidence of biliary obstruction, three for more than five years and one for more than three years.

Other types of surgical procedures such as cholecystoduodenostomy and cholecystogastrostomy also have been used when the gallbladder remained.

When the entire length of the extrahepatic biliary tract was strictured external biliary fistulas have been established in fifteen cases, and in seven of these the fistulas have been transplanted into the stomach or duodenum. In two such cases, in which external biliary fistulas were established, an internal fistula between the biliary fistula and the duodenum developed, apparently because of necrosis caused by pressure of the catheter

on the wall of the duodenum. Both of these patients are living and are relieved of their biliary obstruction.

The hospital mortality in the series of eighty consecutive cases was 12.5 per cent.

In seventy-seven of the eighty cases, stricture followed previous operations on the biliary tract. In 89 per cent of cases the previous operative procedure was cholecystectomy, in 11 per cent of which simultaneous operations were performed on the common bile duct, whereas in 7.5 per cent the previous operation was a cholecystostomy.

In spite of the encouraging results in the surgical treatment of stricture of the common bile duct, the seriousness of the condition should not be minimized; for, in from 8 to 10 per cent of the cases in which accurate anastomosis could be made between the ends of the duct after excision of the stricture or between the stump of the duct above the stricture and an opening made in the duodenum (choledochoduodenostomy or hepaticoduodenostomy), episodes of biliary obstruction recurred and 19 per cent of the eighty patients died over variable periods of time after returning home.

Council on Pharmacy and Chemistry

REPORT OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT.

PAUL NICHOLAS LEECH, Secretary.

SALYRGAN SUPPOSITORIES AND MERCURIN: A WARNING and ACCEPTANCE OF SALLYRGAN SUPPOSITORIES RESCINDED

Salyrgan, which is sodium [o(hydroxymercurimethoxypropylcarbonyl) phenoxy] acetate, was accepted by the Council (*THE JOURNAL*, Dec. 22, 1928, p. 1995) on evidence presented by the manufacturer, the Winthrop Chemical Company, of its usefulness as a mercurial diuretic. In 1937 the firm presented as a dosage form Suppositories Salyrgan of the following composition: salyrgan 0.4 Gm., corn starch 0.1 Gm., and cocoa butter 1.3 Gm. Since the rectal administration of a mercurial diuretic seemed rational, the Council accepted Salyrgan Suppositories as a dosage form of Salyrgan, and the description was published in *THE JOURNAL*, May 15, 1937, page 1715. For the same reason the Council accepted Mercurin Suppositories, 0.5 Gm., distributed by the Campbell Products, Inc., and its description was published in *THE JOURNAL*, July 10, 1937, page 133. Mercurin is a mixture of 20 per cent of the β -methoxy- γ -hydroxymercuri-propylamide of trimethyl cyclopentane dicarboxylic acid and 80 per cent of its sodium salt.

Subsequently Dr. Arthur C. DeGraff, professor of therapeutics at New York University, sent the following communication to the Editor of *THE JOURNAL*, who in turn referred it to the Council on Pharmacy and Chemistry:

For the past year on the Third Medical (New York University) Division of Bellevue Hospital we have been studying the effects of mercurial diuretics when given in the form of a suppository by rectum. When we first began our work the only suppository available was mercurin. In view of the possibility of a local effect on the rectal mucosa, every patient was carefully examined proctoscopically before and after each insertion of a suppository. No untoward effects were noted with mercurin. Early in 1937 Salyrgan suppositories appeared on the market. On May 15, 1937, a notice of the acceptance of the suppository form of Salyrgan by the Council on Pharmacy and Chemistry was published in *THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION*. We decided then that the effect of Salyrgan suppositories should also be included in our study.

Eighteen cases were followed and the condition of the rectal mucosa was noted in each before and after the administration of the Salyrgan suppository. No patient was given a Salyrgan suppository if ulceration, fissure, congestion or other pathologic changes in the rectum were noted.

Of the eighteen patients, eight (44 per cent) showed definite rectal irritation, either a proctitis, ulceration or a marked congestion of the rectal mucosa after the suppository had been given. Three of these

3. Butt, H. R.; Snell, A. M., and Osterberg, A. E.: The Use of Vitamin K and Bile in Treatment of the Hemorrhagic Diathesis in Cases of Jaundice, *Proc. Staff Meet., Mayo Clin.* 13:74-80 (Feb. 2) 1938; Further Observations on the Use of Vitamin K in the Prevention and Control of the Hemorrhagic Diathesis in Cases of Jaundice, *ibid.* 13:753-764 (Nov. 30) 1938.

patients complained of considerable rectal pain and anal tenesmus within twenty-four to forty-eight hours after administration of the Salyrgan suppository.

Because of these results we have discontinued the use of Salyrgan suppositories. Even though this work will be subsequently published in full it seemed advisable at this time to call these facts to the attention of the medical profession generally.

On receipt of this inquiry the Council asked Dr. DeGraff for the lot numbers of the product on which his report had been based. In reply Dr. DeGraff stated:

All the salyrgan suppositories were of lot 4579 and were bought through Eimer and Amend, New York City.

Since I wrote my letter to you I have heard indirectly of a number of other cases of rectal irritation from salyrgan suppositories. In the next few days I will try to get the exact information on these for you.

We have tried to reproduce these results in rabbits but were unsuccessful. The salyrgan suppositories did not seem to cause any damage to the rectal mucosa of the rabbit in four experiments. I give you this information because it is rather important for the referee to understand that the results which we are giving you were obtained in man and not in the laboratory animal.

The Winthrop Chemical Company was informed of this matter and in reply stated:

Your letter of Aug. 11, 1937, has just been received and in view of your request for an immediate reply we quickly reviewed the data collected during the experimental period when extensive investigations were undertaken with Salyrgan Suppositories. At the time the observations made not only referred to the efficiency of this preparation but also to any by-effects which might follow its use. The investigations were entrusted to physicians whose ability and facilities for carrying out the required work are unquestioned. While there were some instances of irritation, the greatest number of patients experienced no discomfort and many continued to use these suppositories over a long period of time. We received no reports of ulceration then or since the commercial introduction, notwithstanding the great number of cases in which Salyrgan Suppositories have been used. We are unable to explain the occurrence of ulceration in one of the cases mentioned in the series discussed in your letter, except upon the basis that there was present some unrecognized underlying pathology in the rectum or perhaps that the patient's mucosa was unusually sensitive to the drug.

In view of the instances of irritation which occurred during the experimental period, and in view of the irritating qualities in high and concentrated dosages of mercurial preparations, we continued the investigations even after the commercial introduction of Salyrgan Suppositories, as it is our aim to reduce the possibility of any damage to the rectal mucosa still further. To date, however, we have found no combination as satisfactory as the one now marketed.

In a reply to a subsequent request from the Council office for the names of investigators who are working with the preparations, the firm sent a list of ten physicians. A communication was sent from the Council office to these men and also to some others, asking whether or not they had observed untoward symptoms similar to those mentioned by Dr. DeGraff. Replies were received from seventeen inquiries. Three of these (not from the list submitted by the firm) stated that they had had no experience with Salyrgan Suppositories. The following are considered to be typical excerpts from the replies received:

1. "I have knowledge of four patients who received Salyrgan suppositories. All complained of subjective distress. In one instance this was very severe."

2. "Salyrgan suppositories have been used in only thirty-one or thirty-two cases. Marked rectal irritation was noted in three cases. In two other cases slight rectal bleeding was noted. It has been found that preliminary irrigation is of value in preventing local irritation and it is employed routinely."

3. "As I told Mr. Smoot they seem to be about half as effective as salyrgan intravenously and would therefore prove of great value were it not for the fact that they so frequently produce rectal irritation."

4. "The Winthrop Company sent enough material for clinical work on ten patients. However, the material was used only on eight patients. The rectal irritation was so marked and the anal tenesmus so prolonged that it was decided to discontinue any further experimental work. Of the eight patients given the Salyrgan suppositories, five complained of considerable rectal pain."

5. "We have not used the suppositories and our records show only two patients who had used them before coming into the hospital. Both mentioned the fact that they had considerable irritation as a result of the use of the suppositories."

6. "I wish to state that I have had no extensive experience with them. I have witnessed their effect on several patients and my experience has been that the effect is not so satisfactory as that following intravenous use and in many instances, because of rectal irritation or other factors, sooner or later one has to change to intravenous use."

7. "They were used in about twenty-four cases. . . . In three of the patients, however, the use of the suppositories had to be discontinued because of the rectal burning, which they complained of bitterly."

8. "We received some salyrgan varying from 200 to 500 mg. . . . During the year these have been administered to some twenty-five patients, approximately fifty of the suppositories being used. The majority of these contained 400 to 500 mg. salyrgan and also contained as a local anesthetic 10 per cent. anesthetin. . . . The general impression is that they did not produce more in the way of rectal irritation than mercurin suppositories which we have used in a comparable series of patients. There were several instances where the use of the suppositories was followed by transient diarrhea and in one or two instances by rectal bleeding. The latter occurred in a patient who had hemorrhoids. A few of the patients complained of transient rectal irritation and burning. We have not used any suppositories containing salyrgan without a local anesthetic. . . . From our experience we feel that no patient should be given a mercurial suppository as a diuretic

who has any symptoms of rectal irritation or who has hemorrhoids. . . . it is our impression that patients have not had more rectal discomfort with the salyrgan suppositories that we have used than with the mercurin suppositories. The incidence of those who did experience discomfort sufficient for them to complain about may be estimated at something less than 10 per cent."

A report on rectal irritation following the use of mercurial diuretics in suppository form was submitted by Dr. Arthur C. DeGraff. An abstract of this is appended. Dr. DeGraff and his associates concluded from their investigation that "Salyrgan suppositories appear to be more irritating than Mercurin suppositories," and "the fact that severe ulceration occurred in three patients out of eighteen would suggest that this dosage form of Salyrgan is inadvisable."

Dr. J. Hamilton Crawford also submitted a preliminary report on local effects of Mercurin and Salyrgan Suppositories. He offered no comment on the results obtained with Mercurin suppositories, for at the time of submission he could report on only two cases in which mercurin suppositories was administered. He reported, however, that of seven patients treated with Salyrgan suppositories two developed definite ulceration. One of these had a normal mucosa prior to administration of the suppositories and one had slight hyperemia before medication.

The Council considered the foregoing and voted (1) that the acceptance of Salyrgan Suppositories be rescinded without prejudice pending the receipt of further reports from the manufacturer; (2) that acceptance of Mercurin be continued but that it be rescinded at any time should evidence become available entailing the necessity of such action as provided in the Council's rules, and (3) that publication of the foregoing report and a warning as to the local irritating effects of both drugs be authorized. The Council, of course, will be ready to reconsider Salyrgan suppositories at any time when it can be shown that their therapeutic action is not complicated by deleterious effects on the rectal mucosa.

The report of Dr. DeGraff and his associates is appended.

RECTAL IRRITATION FOLLOWING THE USE OF MERCURIAL DIURETICS IN SUPPOSITORY FORM

ARTHUR C. DEGRAFF, M.D.; MAX COWETT, M.D.
AND
ROBERT C. BATTERMAN, M.D.

For the past year the effects of mercurial diuretics, when given in the form of a suppository by rectum, have been studied on patients with congestive heart failure. In view of untoward local effects that occurred with the use of one of the preparations now on the market, it seems advisable to report our results in this respect.

Two mercurial diuretics have become available in suppository form for the treatment of edematous conditions. The first to be introduced, in 1934, by Engel¹ is that of Mercurin.² The second preparation is that of Salyrgan.³

The only mercurial suppository for which, at the present time, there are any references in the literature, is that of Mercurin. Numerous reports⁴ are in favor of the clinical efficiency and usefulness of this preparation. In addition, rectal irritation appears to be minimal, for other than a slight "burning" of the mucosa there is no reference to local toxicity.

Because of the possibility of rectal irritation following the insertion of the suppository, the local effects were carefully studied by means of the proctoscope. Each patient was examined before and within forty-eight hours after the insertion of

1. Engel, K.: Peroral Administration of Novurit, Orvosi hetil. 78: 940, 1934.

2. The suppositories were obtained from a local pharmaceutical supply company. Three different supplies were used. Their lot numbers are unobtainable.

3. The suppositories were obtained from a local pharmaceutical supply company, and were of lot 4579.

the suppository. No patient was given the preparation if ulceration, fissure, congestion or other pathologic changes in the rectum were noted. A patient receiving one preparation never received the other. A cleansing enema of plain water was given in each case prior to the insertion of the suppository. In all, fifteen patients received Mercurin and eighteen patients received the Salyrgan suppository.

RESULTS

The proctoscopic observations and subjective symptoms of each patient are presented in the accompanying tables. Five of the fifteen patients receiving Mercurin experienced a "burning" sensation, which in all cases but one was described as slight. In two of these five, in addition, the suppository was expelled shortly after its insertion. None of the patients exhibited any alteration of the rectal mucosa as visualized by the proctoscope.

The Salyrgan suppository, on the other hand, was definitely more irritating to the rectal mucosa. Ten patients of eighteen complained of "burning," pain or itching about the rectum. Three had severe rectal pain and anal tenesmus within twenty-

18	Burning.....	Mucosa injected

four to forty-eight hours after the administration of the suppository. Eight (44 per cent) showed definite rectal irritation, either a proctitis, ulceration or a marked congestion of the rectal mucosa.

COMMENT

The marked local irritative properties of mercurial diuretics must be carefully considered before the preparation is to be used. Any drug advocated for clinical usage should be as free as possible from untoward side reactions. Such reactions often invalidate a preparation which otherwise would be of value. There is no doubt that Salyrgan is an efficient diuretic, but its high local toxicity on the rectal mucosa is a decided disadvantage for the administration of the drug in suppository form. Because of our results, we have discontinued the use of Salyrgan suppositories.

CONCLUSIONS

1. Salyrgan suppositories appear to be more irritating than Mercurin suppositories.

2. The fact that severe ulceration occurred in three patients of eighteen would suggest that this dosage form of Salyrgan is inadvisable.

Council on Foods

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT.
FRANKLIN C. BING, Secretary.

ALLOWABLE CLAIMS FOR THE VITAMIN AND MINERAL CONTENT OF CANNED FRUITS AND VEGETABLES INTENDED FOR INFANT FEEDING

It is desirable that canned sieved fruits or vegetables, prepared for the feeding of infants or for special diets, should retain as much as possible the vitamin and mineral content of the raw fruits or vegetables from which they are made.

On the basis of available evidence the Council previously recognized the general claim that accepted products in this class "retain in high degree the vitamins and mineral salts of the fresh vegetable (or fruit)," provided the manufacturer was able to furnish satisfactory evidence that the manufacturing process was the most efficient available for the conservation of vitamins. The Council has also held the view that, wherever possible, vitamin claims should be specific and supported by acceptable evidence for the presence of the individual vitamins in the quantities claimed. Such evidence of the actual potency of the finished product is particularly necessary for those vitamins which are known to be affected or which may be affected by manufacturing processes.

It is now known that in the canning of fruits and vegetables the inorganic salts and some of the vitamins can be retained whereas it is more difficult to conserve vitamins B₁ and C, at least in many products. Methods of assay have been developed to a point at which the Council believes it is feasible to require that advertising claims, at least for the vitamin B₁ and the vitamin C content of canned strained foods, should be based on assays of the individual product. Accordingly the following General Decision has been adopted:

ALLOWABLE CLAIMS FOR THE VITAMIN AND MINERAL CONTENT OF CANNED STRAINED FOODS

Sieved fruits and vegetables prepared for the feeding of infants or for special diets for older children or adults should retain in highest degree compatible with efficient manufacturing methods the vitamin and mineral content of the raw fruits and vegetables from which they are made. Sufficient experimental evidence has accumulated to warrant the view that vitamins A and G (riboflavin) are little affected by good modern canning procedures. It also seems reasonable to believe that very little of the natural mineral content of the food is lost in canning because no liquid other than that in which the food is blanched is discarded after the vegetables have been washed and otherwise prepared for canning. However, there is evidence that vitamins B₁ and C are more or less adversely affected by canning processes, the degree of destruction depending on the characteristics of the food itself, the time and temperature of processing, and possibly other factors. For products for which the Council is in possession of satisfactory evidence that the manufacturing process is designed to preserve vitamins which are easily destroyed by heat and oxidation, or both, the general claim will be recognized that the major portion of the vitamins A and G (riboflavin) and the mineral content of the fresh food is retained. On the other hand, claims for the retention of vitamins B₁ or C or for retention of vitamins in general cannot be recognized unless supported by acceptable evidence of the potency of the finished product. Determination of vitamin C by titration with 2,6-dichlorophenolindophenol will be acceptable for products for which it has been demonstrated that the results of chemical titration are in close agreement with the results of biologic assay. Bio-assays of vitamin B₁ potency will be necessary.

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COUNCIL ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION AND WILL BE LISTED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED.

FRANKLIN C. BING, Secretary.

SUN-JUCE BRAND ORANGE BASE

Manufacturer.—Fliedner-Kersten Corporation, Los Angeles.

Description.—A canned, pasteurized orange base which may be used in the preparation of sherbet, cakes, icings, pastries and confections; contains ground, unpeeled Valencia oranges, dextrose, water, citric acid (U. S. P.) and citric pectin.

Manufacture.—Formula proportions of dextrose are dissolved in a large amount of hot water. Citric acid and pectin are added and the hot mixture is agitated until solution is complete. The mixture is then deaerated and cooled under reduced pressure.

Selected, tree-ripened Valencia oranges of standard grades (not culls) are washed automatically with revolving brushes under high pressure water-sprays. (No spray materials have been used on the oranges but "scale" is controlled by fumigation.) The whole (unpeeled) fruit is coarsely ground with a portion of the dextrose-citric acid-pectin solution. The remainder of the dextrose-citric acid-pectin solution is added and the entire mixture is passed through a colloid mill. Additional citric acid and water are added and the entire batch is thoroughly mixed and pasteurized at 82 C. for thirty minutes. The enamel-lined cans are filled and sealed under vacuum and cooled immediately.

Analysis (submitted by manufacturer).—Moisture 68.2%, total solids 31.8%, ash 0.3%, fat (ether extract) 0.1%, protein (N \times 6.25) 0.7%, sucrose 0.3%, reducing sugars as invert sugar 20.2%, crude fiber 0.6%, carbohydrates other than crude fiber (by difference) 23.9%, pH 1.6, total acidity as citric acid 6.2%, alcohol precipitate (pectin substances) 13.5%, vitamin C (dye titration) 0.017%.

Calories.—0.99 per gram; 28 per ounce.

BEECH-NUT CHOPPED FOODS (CARROTS, BEETS, GREEN BEANS, SPINACH, PRUNES AND VEGETABLE SOUP)

Manufacturer.—Beech-Nut Packing Company, Canajoharie, N. Y.

Description.—(1) Canned, chopped carrots, slightly seasoned with salt. (2) Canned, chopped beets, slightly seasoned with salt. (3) Canned, chopped green string beans, slightly seasoned with salt. (4) Canned, chopped spinach, slightly seasoned with salt. (5) Canned, chopped prunes. (6) Canned, chopped vegetable soup containing carrots, celery, cabbage, tomatoes, rice, barley and onion, slightly seasoned with salt.

Manufacture.—(1) Fresh carrots are washed, mechanically peeled, hand-scraped and chopped. Water and a small amount of salt are added and the carrots are precooked under steam pressure. Glass jars are automatically filled, sealed and heat processed.

(2) Fresh beets are mechanically washed and peeled, sorted by hand and chopped. Water and a small amount of salt are added and the beets are precooked and canned as described for Beech-Nut Chopped Carrots.

(3) Fresh green string beans are washed, stems and blossom ends are removed by hand and the beans are chopped. Water and a small amount of salt are added and the beans are precooked and canned as described for Beech-Nut Chopped Carrots.

(4) Canned, unseasoned spinach packed in California for the Beech-Nut Packing Company is chopped and a small amount of salt is added. The chopped spinach is precooked, and canned as described for Beech-Nut Chopped Carrots.

(5) California dried prunes are soaked overnight, washed, and simmered in an open kettle in a small amount of water for one-half hour. The pits are removed and the prunes are chopped, precooked and canned as described for Beech-Nut Chopped Carrots.

(6) Carrots, celery, cabbage and onions are washed and the carrots are scraped. Formula proportions of these vegetables

are chopped together and mixed with weighed amounts of rice and barley which have been precooked for one-half hour. Canned tomato purée and a small amount of salt are added, and the mixture is precooked and canned as described for Beech-Nut Chopped Carrots.

Analyses (submitted by manufacturer).—

CLAPP'S STRAINED BEEF WITH VEGETABLES AND RICE AND BARLEY

Manufacturer.—Harold H. Clapp, Incorporated, Rochester, N. Y.

Description.—Canned, strained mixture of tomatoes, beef, potatoes, carrots, unpolished rice, celery, whole grain barley, salt and onions.

Manufacture.—Selected beef U. S. Inspected and Passed by the Department of Agriculture is trimmed free of fat and sinew and ground at the packing plant through a disk with one-eighth inch perforations. The ground meat is packaged and shipped in the frozen state to the Clapp plant, where it is again examined by federal meat inspectors and used immediately. Tomatoes, potatoes, carrots, celery and onions grown and harvested under the supervision of the company are cleaned and the potatoes and carrots are mechanically peeled. Rice and barley are inspected and washed. The ingredients in formula proportions are mixed, precooked under pressure with live steam, strained in an atmosphere of steam, adjusted to standard moisture content, filled into cans, sealed and heat processed. Fresh vegetables are used in season; tomatoes and carrots canned at the company plant are used for off-season packing.

Analysis (submitted by manufacturer).—Moisture 86.3%, total solids 13.7%, ash 1.3%, fat (ether extract) 0.9%, protein (N \times 6.25) 4.2%, crude fiber 0.3%, carbohydrate other than crude fiber (by difference) 7.0%, calcium (Ca) 0.012%, phosphorus (P) 0.056%, iron (Fe) 0.0018%.

Calories.—0.53 per gram; 15 per ounce.

Vitamins.—Although no evidence has been provided the Council as to the vitamin content of this product, the methods of preparation and processing are designed to retain the natural vitamin values to the highest degree consistent with adequate and safe heating processes. Contact of the product with air during processing is avoided as far as possible.

CELLU BRAND GRAPEFRUIT JUICE

Distributor.—Chicago Dietetic Supply House, Inc., Chicago.

Description.—Canned grapefruit juice packed without added sugar.

Manufacture.—Florida grapefruit is washed and halved and the juice is removed by reaming. In hot weather the fruit is cooled before extraction to prevent fermentation. The juice is strained and pumped into temporary storage tanks. Cans are filled automatically by the so-called vacuum process, sealed and heat processed.

Analysis (submitted by distributor).—Moisture 92.2%, total solids 7.8%, ash 0.2%, fat (ether extract) 0.4%, protein (N \times 6.25) 0.4%, crude fiber 0.01%, carbohydrates other than crude fiber (by difference) 6.8%, invert sugar 6.4%, sucrose 0.2%.

Calories.—0.3 per gram; 9 per ounce.

THE CASE OF ASA BRUNSON VS. MORRIS FISHBEIN

(Continued from page 145)

DEPOSITION OF E. W. SCHOEFFEL

Mr. Harrell:—We would like to read the deposition of E. W. Schoeffel, a chemist. It is perhaps a little out of order, but we will connect it up a little later.

The deposition of E. W. Schoeffel, taken on the 25th day of May 1939, at 10 a. m., at room 1540, No. 10 South LaSalle Street, Chicago, Illinois, before Thomas Lewis, was then read in evidence as follows:

E. W. Schoeffel, called as a witness on behalf of the defendant herein, having been first duly sworn by the notary, was examined and testified as follows:

DIRECT EXAMINATION

By Mr. Redmond:

E. W. Schoeffel, Chicago, Illinois, chemist for the American Medical Association Chemical Laboratory, stated that he graduated from the University of Hohenheim, Munich, in basic sciences and received the Ph.D. degree from the University of Wisconsin in 1933. Since receiving the Ph.D. degree at the University of Wisconsin he did chemical patent work for the Wisconsin Alumni Research Association from 1933 to 1936. From 1936 to the present date he has been employed at the American Medical Association. He examines products which are sent in by physicians and examines and standardizes products sent to the Council on Pharmacy and Chemistry of the American Medical Association; also research work derived from further investigation of such products. He then related how he received from Mr. Frank P. O'Hara on June 27, 1938, in the presence of Mr. Edward M. Burke, Mr. O'Hara and Dr. Paul Nicholas Leech, part of the contents of three bottles. He transferred part of the contents of those bottles to bottles which were labeled A, B and C, empty and clean.

Q.—And what if any precautions did you take to insure that no one had access to the liquid or substance which you received from Mr. O'Hara, except yourself? *A.*—During the time I did not work on the substances; they were placed in a safe, to which only I have the key.

Q.—What, if any, analysis did you make of the liquids or the substances which you received from Mr. O'Hara? *A.*—I made a physical and chemical determination of the properties of the liquids.

Q.—Recite the result of your analysis, if any, of the liquids which you received from Mr. O'Hara. *A.*—May I refer to my records to refresh my recollection?

Mr. Quaid:—Right there, before any report is made, this isn't connected up in any way; so far as the record now is concerned it is absolutely immaterial.

The Court:—Counsel said that connection would be made; he said it was out of order. Go ahead. The statement to the Court was counsel would connect it up. Counsel may state to the Court the manner in which you expect to connect it up.

Mr. Harrell:—I expect to introduce the testimony of Mr. O'Hara that he received this medicine from Dr. Brunson and that he turned it over to Dr. Schoeffel.

The Court:—The plaintiff was on the stand and testified with reference to the medicine being given to Mr. O'Hara, and when he started to use it, and with that assurance that counsel would connect it up by Mr. O'Hara, possession of it and that he delivered it to this chemist I will overrule the objection.

Q.—Yes. Do you have an independent recollection of all the results of your chemical analyses? *A.*—Yes, I have.

Q.—Will you recite the result of your analysis, if any, of the liquid which you received from Mr. O'Hara? *A.*—The samples A, B and C appear similar in taste and smell and in physical properties. These physical properties are optical activity and index of refraction. I observed a chemical resemblance through analysis indicating the presence of approximately 95 per cent mineral oil and approximately 5 per cent of volatile terpene-like substances like oil of eucalyptus, mint camphor and traces of terpene-like substances resembling oil of pine and thymol.

Q.—As a result of the analysis which you made of the liquids which you received from Mr. O'Hara, please tell us all of the ingredients or substances contained in said liquids. *A.*—That has been discussed in the foregoing statement.

Q.—Will you recite them again? *A.*—The three liquids received from Mr. O'Hara appear identical in physical and

chemical characteristics. My chemical analysis gave evidence that approximately 95 per cent mineral oil is present. A further analysis by me indicated approximately 5 per cent of volatile terpene-like substances resembling oil of eucalyptus, mint camphor and steam distillable terpene-like substances, resembling in taste and smell oil of pine and thymol.

Q.—Doctor, you mentioned "optical activity." *A.*—Optical activity.

Q.—Will you explain what you mean by optical activity? *A.*—By optical activity I mean the turn of the angle of polarized light of a substance when measured in the precision polarimeter at 25 degrees celsius and at the wavelength of the sodium light.

Q.—What do you mean by "index of refraction"? *A.*—By index of refraction I understand the angle of light reflected by which liquids differ from other liquids.

Q.—As a result of your analysis of the liquid which you received from Mr. O'Hara, have you an opinion within a reasonable degree of chemical certainty as to what was the contents, substance and ingredients of and in said liquids? *A.*—Yes, I have an opinion.

Q.—And what is that opinion? *A.*—In my opinion, these liquids contain approximately 95 per cent mineral oil and approximately 5 per cent of volatile terpene-like substances, such as oil of eucalyptus and mint camphor.

Q.—Did you make a report of your analysis of said liquids which you received from Mr. O'Hara to any officer or official of the American Medical Association? *A.*—Yes, I did so.

Q.—And to whom did you make such a report? *A.*—I made that report to Dr. Leech and in this report included a synthetic mixture which duplicated in smell, taste and appearance the three said liquids under investigation.

Q.—Will you explain what you mean by synthetic mixture? *A.*—By synthetic mixture I understand the mixture which was made up from the knowledge gained by my analysis and duplicating smell, taste and the index of refraction of the liquid under analysis.

Q.—Do I understand that you took some mineral oil, 95 per cent mineral oil and 5 per cent of volatile terpene substances and mixed the two together in an effort to duplicate the liquids which had been presented to you for analysis? *A.*—Yes, I did. I added 95 per cent mineral oil, 0.5 Gm. of menthol, 2.5 cc. of oil of eucalyptus, with an approximately 80 per cent cineol content, approximately 2 to 5 drops of oil of pine and approximately 1 to 2 drops of oil of thyme per hundred cubic centimeters. This mixture on standing and at the time of making resembled said liquids A, B and C in taste and smell, in specific gravity and index of refraction closely, so that I and various members of the laboratory were not able to detect any distinguishable differences.

Q.—Do you believe that the synthetic mixture which you prepared was the same as the substance which had been submitted to you and previously described by you as liquids A, B and C? *A.*—I would say that they resemble each other in taste and smell and physical characteristics to a very close degree.

Q.—Is that degree close enough to lead you to believe that they were practically identical substances? *A.*—In the field of terpene chemistry a definite statement of exact duplication is out of the realm of certainty, but in my opinion they were practically identical substances.

There was then submitted in evidence a detailed report of Dr. Schoeffel's analysis of the specimens concerned.

Wednesday, May 31—Afternoon Session

Mr. Quaid:—We will now read the cross interrogatories propounded to Dr. Schoeffel.

WRITTEN CROSS INTERROGATORIES

Propounded by the Notary:

After questions identifying the witness, interrogatories proceeded:

Cross Interrogatory No. 10:—If you say you analyzed the said fluid, state the period of time that was consumed in your analysis? *A.*—Approximately two months, but this total time was not always taken up with the analysis for these liquids, but

it comprised the period of the analysis for these liquids. A rough approximation of time; should the analysis be done in consecutive time, may be approximately a week and a half.

Cross Interrogatory No. 14:—Who paid you for making the analysis, and how much? *A.*—The American Medical Association pays my salary. There is no payment for analysis itself, since I am on a salary employed basis.

Cross Interrogatory No. 16:—Did you find carbon, hydrogen, oxygen and possible nitrogen, in your analysis? *A.*—I found that the liquids contained combustible material with a practically negligible ash content and with no definite indication of readily detectable nitrogen.

Cross Interrogatory No. 17:—State how much of each element you found in your analysis. *A.*—No combustion analysis was performed. An approximate group analysis, or analysis of constituents, was performed.

Cross Interrogatory No. 18:—Could you actually determine each ingredient? If so, name same. *A.*—The ingredients were determined and I found that approximately 95 per cent mineral oil as a base and approximately 5 per cent volatile terpene-like substances were present in the liquid.

Cross Interrogatory No. 20:—Approximately how many organic substances exist? *A.*—In this substance under investigation a chemical analysis shows that there are at least one definitely determined constituent, which is mineral oil, approximately 95 per cent, and approximately 5 per cent of volatile terpenes, such as oil of eucalyptus or mint camphor. If the question means organic chemicals in existence, we have approximate 400,000 organic chemicals.

Cross Interrogatory No. 21:—If you state there are approximately 100,000 organic substances, state how many test tubes you had to use for the purpose of ascertaining whether or not any of those 100,000 organic substances were in the formula. *A.*—The question is below the dignity of the court. Such an analysis has never been performed and is not performed.

Cross Interrogatory No. 22:—To ascertain an unknown organic substance, when you have no idea what that substance is, the tester takes the analysis of all organic substances, does it not? *A.*—No.

Cross Interrogatory No. 23:—To accomplish this, when several gallons of the fluid are being analyzed, it would be necessary to make a complete chemical test? *A.*—It is rarely the case that several gallons are used for chemical analysis. In many cases it is sufficient to use a smaller portion, approximately 5 to 10 cc., which gives adequate knowledge as to the constituents named therein.

Cross Interrogatory No. 24:—Is it a fact that, when you analyze for a substance, the chemical under intense heat carbonizes, and it is necessary, in continuing your hunt, to get a new sample of the medicine? *A.*—Yes, under intense heat, organic chemicals break down. But at the same time the expert can obtain valuable information as to the contents under analysis. A careful chemist does not investigate all of his product under investigation in one investigation but keeps sufficient material for repetition of his tests and for further examination, should a combustion have yielded him information which leads to further analyses.

Cross Interrogatory No. 25:—State how much of the formula you used for each experiment when you were looking for an unknown drug in 100,000 existing possibilities. *A.*—There are various ways by which a trained expert will use his technical skill in investigating a product under analysis. Present day scientific methods may use as little as 0.1 cc. or its equivalent in weight to make a complete investigation, as far as chemical evidences may carry. In my tests I used from 0.1 to 5 cc. depending on the various tests under investigation.

Cross Interrogatory No. 26:—Can any chemist tell from an analysis whether a medicine compound is, or is not, physiologically incompatible? *A.*—A skilled expert, with the necessary, requisite training, is able to find incompatibilities of various medicines, should such exist, within the scope of present day chemical knowledge.

Cross Interrogatory No. 27:—State whether or not any medicine is chemically incompatible but not physiologically so. *A.*—This question is out of my realm of activity and belongs to the clinical physiologic expert.

Cross Interrogatory No. 28:—Is it not a fact that, when they are incompatible chemically but not so physiologically, that they are successfully employed by physicians? *A.*—I would give the same answer as before.

RE-DIRECT EXAMINATION

By Dr. Redmond:

Q.—Doctor, into how many groups are the 400,000 organic substances divided? *A.*—Organic chemistry is the chemistry of carbon and its substitution products. As such, it is developed into a most logical science of classification. Organic chemicals can be grouped into three definite classified systems, namely acyclic, cyclic and heterocyclic. Each group is in turn sub-classified. With this classification it is possible to distinguish readily between the various group members of various systems. Terpenes as found in certain products are a group belonging mainly to the group of the cyclic system and, as such, have various characteristics which are detectable with ease by the trained chemist.

Q.—By that, do you mean Doctor that, in order to determine what organic compound is present in a substance submitted to you for examination, it is not necessary to make a separate test for each of the known organic substances? *A.*—No. Such an analysis is not made.

Q.—Do you mean, Doctor, that it is possible to determine by chemical analysis the presence of a particular group of organic substances? *A.*—Yes, it is.

Q.—And then, when you talk of a subdivision, do you mean that in that particular group additional tests are made to determine which one of the members of the group is present? *A.*—Yes, there are.

Q.—Was organic chemistry originally conceived to be the chemistry of the carbon compounds? *A.*—Not until the year 1860, when Kekule announced the discovery of the ring system.

Q.—So, organic chemistry at the present time means the chemistry of the carbon compounds? *A.*—And their substitution products.

Q.—Do most of the organic substances contain carbon and one or more of the following elements: hydrogen, oxygen, nitrogen, sulfur, chlorine, bromine, iodine and phosphorus? *A.*—Organic chemicals are classed in respect to their carbon and hydrogen content and are classified in respect to their additional or substitution products.

Q.—Doctor, when you were making your examination of the substances which had been submitted to you by Mr. O'Hara did you need any further samples than that which you had been furnished? *A.*—No, I did not.

Q.—Did you have sufficient for your purpose? *A.*—I had sufficient and I have still retained a small quantity.

TESTIMONY OF DR. L. J. MOORMAN: ON
DIRECT EXAMINATION

Questions by Mr. Reynolds:

Dr. L. J. Moorman, Oklahoma City, practices in internal medicine, with special attention to the diseases of the lungs. He is medical director of the Farm Sanatorium for the treatment of lung conditions. He entered medical school with a B.S. degree and graduated in medicine from the University of Louisville, Ky. After graduation in 1901 he went to New York City for postgraduate work in 1903. In 1906 he went to the University of Virginia for graduate work in laboratory and to review medicine. In 1909 he went to Europe for postgraduate work and spent seven months in the University of Vienna, studying medicine with special attention to pathology, and in that line particularly with reference to pathology of the lungs and the respiratory system. He visited hospitals in London and Liverpool. He went to Boston for special work in tuberculosis, and then to Saranac Lake for some work. Since then he has attended the medical meetings and visited clinics and hospitals all over the country. He is a member of the county medical society, the state medical association, the American Medical Association, the American Climatological and Clinical Association, the Southern Medical Association, and the National Tuberculosis Association and American Sanatorium Association. He is now vice president of the American Sanatorium Association. He is a member of the Oklahoma City Academy of Medicine, the state tuberculosis association, and has been president of the Oklahoma City Tuberculosis Association for twenty-two years and director of the Tuberculosis Dispensary in Oklahoma City for twenty-two years.

Q.—Doctor, in this regard, is there any agency in this country which classifies or certifies specialists in the field of tuberculosis? *A.*—Well, there is the American Board of Internal Medicine, which does standardize and classify physicians in internal medicine, with special attention in tuberculosis; that is the way I am classified.

Q.—Are you certified to that board as a specialist in tuberculosis? A.—Yes, I am. I think I failed to mention a while ago that I am a member of the American College of Physicians.

Q.—Now, Doctor, will you tell us the hospitals and institutions with which you have been or are now connected in tuberculosis work? A.—Well, I am now medical director of the Farm Sanatorium and have been for twenty-six years; I have been connected with the University of Oklahoma School of Medicine for—I was there about eighteen or twenty years, and taught physical diagnosis and was clinical professor of medicine for several years, being advanced from lower positions. I was dean of the Medical School for three years and was superintendent of the University Hospital and Crippled Children's Hospital, those two institutions having about 400 beds, and there I had the direction of the—taught physical diagnosis and had direction of the diseases of the chest in the hospital wards and also supervision over the hospital in general and attended the postmortem findings in connection with the University Hospital.

Q.—Doctor, will you state the nature of this Farm Sanatorium, with which you are connected, how many patients it accommodates and how many beds it has? A.—For a time we had fifty beds, with an average of about forty-five patients; in the last ten years the number has been reduced and we now are using twenty-five beds.

Q.—Doctor, have you ever had original articles written by yourself accepted for publication in medical or other journals? A.—I have.

Q.—How many on the subject of tuberculosis, just in a general way? A.—I should think twenty or thirty.

Q.—And over what period of years? A.—Over a period of twenty-five years.

Q.—In what journals, just name a few of them? A.—Well, I have had articles published in my state journal, state medical journal, in *THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION*, the *Minnesota State Medical Journal*, the *Kansas State Medical Journal*, in the *American Review of Tuberculosis*, in *Annals of Internal Medicine*, which is the official publication of the College of Physicians, and in *Annals of Medical History*. I wrote a chapter on gas hazards in connection with the production and refining and consumption of petroleum and its products for Oxford Medicine. That covers the field, I think, pretty well.

Q.—Now, Doctor, have you ever been called before to testify as an expert in cases involving alleged tuberculosis cures? A.—Yes, sir, I have.

Q.—Will you tell us what occasions? A.—In 1918 I was requested by the federal government to go to San Antonio to testify in connection with an alleged cure of tuberculosis, which was an inhalation cure, so-called Thompson cure. I have testified repeatedly before the Oklahoma State Industrial Board in cases having to do with injuries to the thorax or the chest, and some of them where tuberculosis was the main factor in the case.

Q.—Doctor, how many autopsies have you performed or observed during the time that you have been specializing in tuberculosis? A.—I could not state definitely, but hundreds, I would say.

Q.—And over what period of time? A.—Over twenty-five years' time.

Q.—Have you observed any recently or performed any recently? A.—I have. Hardly ever a month goes by but what I perform or observe autopsies.

Q.—Now, Doctor, will you tell us how you became interested originally in the subject of tuberculosis? A.—Well, I became interested originally because I was practicing medicine in Oklahoma City, associated with two surgeons with a statewide reputation and practice, and at that time, thirty-one or thirty-two years ago, the state of Oklahoma was largely populated by young people, many of them having no homes, and at that time there was a great popularity with the idea of climatic treatment, and my association with these surgeons placed on me the responsibility of every medical examination and medical decision with reference to referred cases, and I felt like I was living in a good climate and didn't wholly share the idea that people, to get well of tuberculosis, should go west, and it was in a way forced on me because of the fact that I frequently discussed tuberculosis, seeing the need of treatment, and I got interested in the treatment of it, and out of that grew my private institution. I later on had tuberculosis myself, and that enhanced my interest and also my knowledge of the disease.

Q.—How long ago was it that you had tuberculosis? A.—About twenty-four years.

Q.—Doctor, have you made any particular study of the history of tuberculosis and medical developments along that line? A.—Yes, I have.

Q.—I will ask you, Doctor, if it is your opinion in connection with the treatment of tuberculosis that the pus accompanying tuberculosis is the thing at which treatment should be directed? A.—I would say no.

Q.—Will you explain why? A.—Tuberculosis is a disease caused by specific germs or microscopic organisms which enter the body in various ways. The germ has a predilection or predisposition to localize itself in the lung and later in the glandular structure about the root of the lung. It may locate in other parts of the body. It begins its work without influence of any other microscopic organisms and gradually develops tubercles with ultimately the death of the tissue cells, the elimination usually of the blood supply, and while all that is going on, the patient may be having the classic symptoms of tuberculosis and may have some obvious signs of tuberculosis that are to be observed by examination and still not have what we call open tuberculosis with sputum and the germs of tuberculosis in the sputum, and a patient may die from tuberculosis without having purulent sputum. That is particularly true of the type we term miliary tuberculosis, and that comes around usually because the tuberculous process may reach the point of ulceration, we will say, in one of the glands in the root of the lung without any additional or so-called or outside or mixed infection from other bacteria. A lymph gland may ulcerate and rupture through the wall of the blood vessel and give rise to what we call miliary tuberculosis, which may be limited to one organ or may be in the general organs of the body and the patient may be overwhelmed by such a condition without having any sputum or purulent sputum. Meningitis in children, infants and young children may come about in the same way and called. Now, if this tubercle through the death of the tissue softens, as we say becomes necrotic, and lodges in the bronchus, then there may be purulent sputum and the germs of tuberculosis are then found in the sputum but the treatment remains the same as it would if this had never happened, and the arrestment or clinical cure of tuberculosis rests on the same principles of treatment. These so-called pus producing bacteria give rise to so-called mixed infection and are constantly in the respiratory tract and can be demonstrated at any time whether a patient is well or sick.

Q.—In the theory of treating tuberculosis by eliminating pus that, in effect, is an attempt to treat the effect rather than the cause, is that right? A.—I would say that.

Q.—Doctor, is it a new or novel idea to have that theory that treatment of the pus or the effect is the treatment recommended for tuberculosis? A.—No, it is not.

Q.—Do you know when it ever has been advanced before? A.—I do not know when. I can't give dates. If you refer to a treatment by inhalation or spraying, we can date it back approximately 300 years. A physician named Bennett is reported to have employed such treatment as early as 1664. Linick in 1819 tried a similar treatment and others about that time. Then the literature dealing with the history of tuberculosis supplies a long chasm or gap with reference to this method of treatment, as far as I have been able to discover in my studies of the history of tuberculosis. In 1882 the tubercle bacillus was discovered. Even before that time we had discovered that rest was of value in the treatment of tuberculosis and it still is one or the one great factor in treatment of tuberculosis.

Q.—Has this theory of inhalation ever been accepted by the medical profession generally? A.—May I just say a few words before answering that question directly?

Q.—Certainly. A.—I was going on to say with the discovery of the tubercle bacillus and with the discovery that tuberculosis was often curable when diagnosed early enough, there was a great revival in the interest of the treatment of tuberculosis and in the last quarter of the nineteenth century there was a trial of inhalation cures and sprays and somebody a hundred years ago had invented a nebulizer and that was used for this purpose as well as the volatile oils and medicines which might be volatilized and inhaled and it was simply a trial of another agent and revival of something that had been tried before and discarded. By 1915 or 1920 all of this again was given up as far as I am able to determine without any hope of success. That is about the history of the inhalation treatment.

Q.—Do you know why it was discarded? A.—It was tried by some very able men and statistics were accumulated and control cases were followed along with those treated, and there was no definite evidence that it was even aiding in the cure of tuberculosis and that is why it was discarded.

Q.—Now, Doctor, is it your opinion that every human being has the tubercle bacilli in his system? A.—It is my opinion that today we couldn't say that every human being harbors the tubercle bacillus in his body. That was taught in the past by some very good authorities but we have a way of determining who has and who has not live tubercle bacilli in the body, that is the tuberculin test, and it is a very accurate test when accurately administered with potent and pure tuberculin and we feel that when there is a positive tuberculin test we may be reasonably sure that live tubercle bacilli are in the body. If the test is negative after at least three attempts with solutions of advancing strength we feel pretty sure there are not any live tubercle bacilli in the body.

Q.—In connection with your work of performing autopsies have you ever examined lungs in which you definitely concluded there were no tubercle bacilli? A.—I have examined lungs where I could find no evidences of active tuberculosis and I have examined lungs where I could find no scar tissue, where I would be suspicious of the presence of tubercle bacilli. In the ordinary autopsy in the gross study of tissues it would be impossible to say that tubercle bacilli are present or absent.

Q.—Now, Doctor, is it your opinion that every person has tuberculosis even though in very slight degree? A.—I think that is not true today. It seems to be less as time goes on. A few children of school age react to tuberculosis and in rural communities we find groups of people relatively free from tuberculosis. In urban population the incidents or the rate of infection rules very high after the population reaches an age level of 18 or 20 years anyway.

Q.—Now, Doctor, is there a specific clinical cure for tuberculosis accepted by medical science today? A.—I doubt if I would be justified in saying there is a specific cure for tuberculosis. The one thing more nearly approaching a specific cure than any other one thing is rest. Rest for early cases approaches the power of a specific in the cure.

Q.—What does specific mean? A.—A specific remedy for disease means a remedy that cures, absolutely cures.

Q.—Medical science does recognize rest, however, as a clinical cure. Is that right? A.—Yes.

Q.—Is there any bacteriologic cure? A.—I would say no.

Q.—By that you understand the meaning to be the eradication of the bacilli? A.—I would be afraid to say definitely that the bacillus in any given case can be eradicated no matter how long we pursue the cure, but I am of the opinion that in some cases that may happen as an ultimate result, but we physicians recognize the fact that although we feel we have effected a clinical cure the tubercle bacillus is pretty apt to remain encapsulated in the organism and may at some future time, particularly if the human organism is placed under undue strain, physical or mental or subjected to other diseases which lower resistance, tuberculosis may return. There may be a reactivity of the apparently healed.

Q.—In your own experience you have experienced a clinical cure. Is that right? A.—Yes, indeed, often.

Q.—I will ask you if this statement is scientifically sound: "It is the pus germ that does the most harm"? A.—I do not think that is scientifically sound.

Q.—On what do you base your opinion? A.—On the statement which I made a few minutes ago about the progress of the tubercle under the influence of the specific cause, the tubercle bacillus.

Q.—In that statement of the progress of tuberculosis from what sources have you or has medical science obtained that knowledge and opinion, from what method? A.—From the clinical study of our patients, including all of the methods which we have for the accumulation of knowledge from a study of gross and microscopic pathology.

Q.—What is the study of microscopic pathology? A.—When I say gross and microscopic pathology we first get all the information we can by inspection of pathologic specimens. By microscopic pathology I mean cellular pathology, and that can be studied only under a powerful microscope and the character of the tissues and cells can be determined by microscopic studies and a great deal of knowledge with reference to the finer characteristics of tubercles has been discovered in that way. Grossly we can tell there is a tubercle, which means a nodule or tumor varying in size, but to know the finer structure we must use a microscope.

Q.—You have done some of that work yourself? A.—I have.

Q.—Now, Doctor, is this statement true: "There is no patient with tuberculosis that does not cough"? A.—That is not true.

Q.—Will you explain why? A.—Because any human being may have tuberculosis in any part of the body, in any organ or any tissue and tuberculosis even in the lung may not be so situated and of such a nature—and it is well to understand that it varies greatly in its manifestations—it may not be so situated and of such a nature as to create the irritation of nerve endings which gives rise to the cough reflex and causes the impulse to cough.

Q.—Now, Doctor, is this statement true: "There is only one type of tuberculosis"? A.—Specifically that may be true if you will refer back to one specific cause, the tubercle bacillus, but I have just said that tuberculosis varies greatly in its location, and its pathologic manifestations and its symptomatology and there are a good many different types of tuberculosis.

Q.—Now, Doctor, in the anatomy of the human body is it true that the larynx opens into the esophagus? A.—No, it is not.

Q.—Is it true that the pharynx opens into the windpipe? A.—I would say that both the windpipe and the esophagus open in the pharynx.

Q.—How about the larynx? A.—And the larynx is the capital of the windpipe or the top of the windpipe and it is through the larynx that the windpipe opens into the pharynx.

Q.—That windpipe you call the trachea? A.—The trachea.

Q.—Is this statement true: "The air cells of the lungs are closed on inspiration"? A.—Not as far as my knowledge goes, that is not true.

Q.—Is it true that the air cells of the lung are open on expiration? A.—The air cells are open on inspiration and on expiration.

Q.—Now, with reference to what are known as the alveoli, what are they, Doctor? A.—Air cells.

Q.—And your answer is the same to that? A.—The same.

Q.—Now, Doctor, in connection with the tubercles where they appear in the larynx, is it physically possible in any patient to see nodules from tuberculosis on the larynx merely by opening the mouth, putting a tongue depressor in the mouth and looking down? A.—I have never seen a case where that could be done.

Q.—In your opinion is it possible? A.—In my opinion it is physically impossible.

Q.—Have you an opinion whether or not tuberculosis of the larynx could be diagnosed by inserting a tongue depressor and looking in it? A.—In my opinion it could not be.

Q.—Now, Doctor, in connection with this next question, I want you to assume a treatment or alleged treatment for pulmonary tuberculosis consisting of the administration of an oily liquid by means of an atomizer to which is attached an oxygen tank, that the pressure gage on the oxygen tank shows the pressure from 35 to 40 pounds, that the tip of the atomizer is placed in the mouth and that the oxygen is released so that it goes through the atomizer and produces a vapor from the oily substance and ten inhalations are made by the person, that this treatment is repeated twice daily, that the composition of the oily substance contained in the atomizer is approximately 95 per cent mineral oil and a 5 per cent volatile terpene-like substance including oil of eucalyptus and menthol, sometimes known as mint camphor, and also terpene-like substances similar to oil of pine and thymol, have you an opinion, Doctor, as to whether or not that treatment might or could have any beneficial effect in the treatment of pulmonary tuberculosis?

Mr. Quaid:—Your Honor, though the field of an expert is pretty wide, we do not believe it is that wide, unless he can give something to show that he has some information about that character of treatment, has used it himself. I do not believe he should be allowed to answer a hypothetical question.

The Court:—He is an expert, he is asking whether on that predicate he could express an opinion. He can say whether he can or not, if he can he can then state what it is.

Mr. Quaid:—We feel a man can testify about the things he has experienced with but he has not shown he has had experience on that matter.

The Court:—That goes to the weight of the testimony: You may interrogate him further. The hypothetical is being propounded to him as an expert, whether he can express an opinion on that predicate, and if he says he can, he can state what it is. It would be admissible. You then have the privilege of testing his ability to answer that question. Exception overruled.

A.—Yes, I have an opinion.

Q.—Will you state what your opinion is, whether it could or might have any beneficial effect as a treatment for pulmonary tuberculosis?

Mr. Quaid:—We renew our objection unless he has had some experience in this line. Even an expert is not supposed to testify to matters he has no experience in.

The Court:—He is himself qualified to treat tuberculosis and he is an internal medicine man. Overrule the exception.

Q.—What is your opinion, Doctor? A.—My opinion is that it could not have beneficial effect, and if I may supplement that answer, it is my opinion it might have a detrimental or harmful effect, and if I may go further, I would qualify that answer by saying that opinion is based on my knowledge of the damage which comes from overworking any inflamed organ. The deep inhalation is bad for an inflamed or diseased lung and that is one reason why rest, either general or local, slows down respiration and makes it more shallow, or rest locally which is brought about by various collapse therapy methods, is one reason why we get benefit because we rest the lung. If you overwork it for the purpose of getting some medical treatment in the bronchi or air cells, you might do harm. If the person goes and comes increases the depth and volume and frequency of respiration and also be harmful. Petroleum or liquid petrolatum or vaseline is an irritant in the lung and in addition, it might have a toxic effect through its retention in the smaller bronchial tubes, air cells and sometimes even produce a pneumonitis or pneumonia. That has been demonstrated time and again. Oil merely dropped into the nostrils, especially in the nostrils of children, may give rise to the pneumonia. At the last session of the American Medical Association there was an exhibit of lungs removed from infants and children showing the evil effects of the inhalation of oils, often to the point of definite pneumonia.

Q.—Doctor, I believe you stated that you have done special work in connection with the effects of working with oil in the lungs? A.—I cannot say I have done special work. It has been used as a diagnosing agent because it is opaque before the x-rays even in the tuberculous. In the early history of its use one of our greatest chest surgeons on this continent, Dr. Archibald of Montreal, warned against its use for diagnostic purpose because he observed that acute inflammatory condition in his patients at times and thought, perhaps, it was a flare-up of the tuberculosis. We are not sure whether he may have been observing a nontuberculous pneumonia from the oil alone or a tuberculous pneumonia from presence of iodine that was in this oil, but in either event the instillation, I might say, in this case of the oil, proved to be harmful. I might go further and say that practically all of the oils and volatile aromatic agents such as you mention, eucalyptus, menthol and thyme, have been employed before and discarded because they did no good and because sometimes it was evidently proved to be irritating to the mucous membrane.

Q.—Now, Doctor, would it make any difference in your answer if that liquid consisted not of the exact terpene-like substances I mentioned but of other similar oils and in different proportion? A.—In my opinion it would make no difference as far as my own judgment is concerned. I would feel it would make no difference.

Q.—Now, Doctor, just tell us what the difference is between subjective and objective symptoms. A.—Subjective symptoms are symptoms which are conceived in the mind of the patient and are presented to the physician by the patient.

Q.—In other words, he tells you how he feels? A.—He tells you how he feels. Objective symptoms are those that are obvious to the examining physician.

Q.—In listening to a man's chest with a stethoscope, that is objective? A.—Yes.

Q.—And the determination made from that is objective? A.—Yes.

Q.—And from x-ray? A.—Objective.

Q.—And from sputum? A.—Objective.

Q.—No subjective to any of those? A.—No.

Q.—In connection with pulmonary tuberculosis what would, for instance, be a subjective symptom? A.—A subjective symptom would be a patient's complaint of pain or nervousness or tickling in the throat or an inclination to cough; that is something I cannot see or feel or hear, but I can hear the patient make the statement.

Q.—Now, Doctor, with reference to this oily solution that I described a minute ago, is there anything in that solution at all that is antiseptic? A.—I do not know just what is in the solution and I know this, that regardless of claims with reference to the virtues of antiseptic solutions, they never enter the throat or respiratory tract to kill the germs without doing harm to the tissue they come in contact with.

Q.—Will you describe to the jury just exactly what happens to a patient suffering with pulmonary tuberculosis, tracing the oil from the entry of the mouth into the lung, if it gets into the lung? A.—You mean what happens in case such a treatment is administered?

Q.—Yes. A.—I would say that the patient is inhaling with a rate and depth of respiration which in all probability is exaggerated and which is not good for the patient, as I have explained. I would say that the patient might first have a sensation of the presence of whatever medicament is being administered and have irritation and inclination to cough immediately. They become more or less adjusted to the process of treatment as seconds transpire and there might be some increase in secretion because of the stimulating and irritating qualities of the drugs administered; but that secretion would not particularly influence the outflow of pus that might be present unless the stimulation of cough might bring it up, but it would be an added secretion or liquid due to the activity of mucous glands. It would be an outflowing of mucus and maybe some increase in expectoration on that account.

Q.—Now, Doctor, what actually happens to the oil? Does it penetrate into the tissues of the body, in your opinion? A.—In my opinion it would not. If any of the oil or accompanying drugs were absorbed by the blood stream or even the lymphatics, that drug, no matter in what form it is carried into the blood or the lymph, would not reach, and certainly would not reach the center of the tubercle, because, as I explained a while ago, as the tubercle develops the blood supply and circulation is cut out of that tubercle and that is what brings about the gradual death of tissue cells in the center of the tubercle. Medicine, even though it enters the blood stream, would not get to the tubercle. Besides, even though it might have some inoperative action, it would not cure tuberculosis because it would not reach the tubercle bacillus, which is in the center of a destructive process, with the facilities for conveyance of the medicine cut off.

Q.—Now, Doctor, how many different types of rales are there to be heard in the lung in cases of tuberculosis? A.—Well, I would say that there is some variation of opinion as to classification of rales, but we think the simplest and most workable for the physician is to classify rales into crackling and musical rales. Crackling rales are further classified into fine, medium and coarse crackling rales, and sometimes have bubbling rales and rales in the bronchial tubes and trachea. Then under the classification of musical rales we would say sibilant, which is very fine wheezing or musical sounds, and sonorous rales, which sometimes are something like moderate snoring sounds. We might say crackling rales are instantaneous, without duration, because if they do have duration, they run on as a musical sound, wheezing, whistling, or fine crackling sounds—

Q.—The presence of rales on stethoscopic examination and increased body temperature and lowered blood pressure may be symptoms accompanying pulmonary tuberculosis, is that correct? A.—Yes, that is true.

Q.—Now, Doctor, may they be present and accompany any other disease or dysfunction other than pulmonary tuberculosis? A.—Quite so, they may.

Q.—How many? A.—Oh, I think several others. One is influenza, especially with a localized pneumonitis, pneumonia, just as we have tuberculosis in early stages or moderately advanced stages, bronchial pneumonia, even lobar pneumonia in certain stages, bronchiectasis, which is an inflammation leading to dilatation of the bronchial tubes and the presence of pus, and others, which would not be so puzzling in diagnosis. I could name periobronchiectasis. Those are among the things. I could name lung abscesses would be another case.

Q.—Then in the complete diagnosis of pulmonary tuberculosis would it or would it not be, in your opinion, the better practice to include discovery of those symptoms, to include with the discovery of those symptoms sputum examination, x-rays and other means of determining the disease? A.—I think that question is leading.

Mr. Reynolds:—I said would it or would it not.

The Court:—Probably is. The question is leading. Counsel will redraft question.

Mr. Reynolds:—I will withdraw the question.

Q.—Doctor, in making a complete examination for the purpose of diagnosing tuberculosis would you include any other examinations than those four? A.—Yes, I would.

Q.—What are they? A.—I would include an x-ray of the chest, which means the lungs, of course, and I would include

examination of the sputum, and if I were not satisfied with one examination I may make twenty or forty before making a final diagnosis, because a decision with reference to treatment is very important. One must first make a diagnosis before he can intelligently treat a case, and in making that differential diagnosis in determining whether it is this, that or the other, we feel that we are not doing justice to our patients first of all, or to ourselves as physicians, until we apply all possible means of making a definite diagnosis. Those means include careful examination of the sputum, and sometimes even culture of the sputum as well as microscopic study of a smear.

Q.—What is culture? A.—Smear the material on a chosen culture medium and place that in an incubator at a desirable temperature for days of observation, produce a growth of the tubercle bacilli if that is what we are looking for, which might not have been discovered under the microscope. If we still feel doubtful we might do an animal inoculation for the purpose of seeing if we can reproduce a disease in a guinea pig, for instance, or a rabbit.

Q.—At one time in connection with treatment for pulmonary tuberculosis there was a theory advanced called an exercise theory; is that correct? A.—That is correct.

Q.—And at what was it aimed? What was the theory? A.—I have often wondered what and why, but it was in vogue in the latter part of the nineteenth century. One Bodington conceived the idea of a modified rest cure for tuberculosis and ventured to write an essay on such a radical procedure. That was the latter part of the nineteenth century. It was such a departure from what had gone on in the past that he was accused of being insane and his little private institution was converted from the purpose of treating chronic cases to an insane asylum. Later on Brehmer, in Germany, discovered this essay and built the first or at least established the first sanatorium for the treatment of tuberculosis. He combined with rest the idea of exercise, had all of his paths so that the patient would walk from the sanatorium up hill, but fearing the harm from exercise, fearing he might go too far and find it too much of a task to return, he gave them a down hill return to make it easier for them. Now, for some time that method was observed, and Dettweiler, a famous physician who was unfortunate enough to be a patient of Brehmer, conceived the idea of more rest because he saw the exercise was doing Brehmer's patients harm instead of benefiting them. He was the first to use the so-called reclining chair so the patient could be in a sanatorium yet move out of doors, and so sit or recline in a chair, and Dettweiler drew away from Brehmer and established his own institution.

Q.—This exercise, would it have anything to do with the elimination of pus? A.—It may have had, but I couldn't say for sure; I don't know about that. It was abandoned as a pernicious method of treatment.

Q.—Doctor, do you know whether or not, from the standpoint of medical literature and medical research, this statement is true with reference to the treatment I described to you in the hypothetical question, that "similar methods tried elsewhere have proved to be failures," methods similar to the inhalation of oil? A.—Yes, as far as I can determine by my contact with physicians over a period of thirty-eight years, and my reading of the history of the treatment of tuberculosis, these things have been tried and abandoned. I remember when they were being tried, and I visited various institutions over the United States and saw the inhalation method with various medicaments in operation.

ON CROSS EXAMINATION

Questions by Judge Sweeney:

Q.—When did you arrive in El Paso, Doctor? A.—Sunday morning, about, I think between 9 and 10 o'clock.

Q.—Doctor, since arriving here who have you talked to with reference to what your testimony would be in this case? A.—I have talked to the attorneys and have talked to some of my doctor friends, just informal discussion of tuberculosis.

Q.—Who have you discussed it with, what doctor friends? A.—Dr. Sam Watson of Tucson, Dr. Corper of Denver, and Dr. Randolph of Phoenix. I don't believe with any one else.

Q.—Did you discuss it with Dr. Hruby of Chicago? A.—Yes, Dr. Hruby. I failed to mention him.

Q.—You discussed what would probably be the evidence in this case with your doctor friends, did you not, Doctor? A.—Well, not so much that. The most of my time here has been spent just visiting with my doctor friends and trying to learn something more about tuberculosis.

Q.—You discussed the inhalation method of treatment? A.—We have, but not particularly in connection with this case.

Q.—With these doctors that you just mentioned? A.—What?

Q.—With the doctors that you just mentioned? A.—Yes.

Q.—Did you talk to any local doctors here? A.—Dr. Egbert.

Q.—Dr. Egbert? A.—Yes. I don't think much about this treatment though.

Q.—Did you discuss this case with Dr. Egbert? A.—Indirectly, yes, sir.

Q.—You told him you were down here to testify in reference to— A.—He knew that before I—I think he indicated that to me when I first met him.

Q.—Now, when did you discuss the case with the attorneys, Doctor? A.—I don't know I can say just when. On two occasions I think, in the hotel.

Q.—You have discussed what you were going to testify to, what questions they were going to ask you, and what responses you were to make? A.—There was some discussion of that.

Q.—Who was present when that discussion took place, Doctor? A.—Mr. Reynolds was present.

Q.—I can't hear you. A.—Mr. Reynolds was present, and two or three of the doctors I mentioned.

Q.—Which particular ones, do you recollect? A.—Dr. Watson and Dr. Randolph.

Q.—Dr. Egbert? A.—And on one occasion Dr. Hruby I think.

Q.—And Dr. Hruby? Now, on that occasion Drs. Watson and Hruby and you were there with the attorneys discussing this case and discussing the evidence in the case, what you were to testify to? A.—Nobody attempted to tell me what I was to testify.

Q.—I didn't state that, Doctor, I didn't state that. I say you were discussing informally the evidence that was to be given in the case? A.—You have changed the question just a little bit.

Q.—Mr. Reynolds was propounding certain questions to you, was he not? A.—I think Mr. Reynolds did suggest what he might ask me, but he did not attempt to tell me what I would say.

Q.—Mr. Reynolds has been reading questions here from this book. Now, were those questions prepared last night or night before last?

Mr. Reynolds:—I am sorry, Your Honor, but I must object to that. I haven't read many questions. I will show counsel my notes.

Judge Sweeney:—I am asking the witness a question.

Mr. Reynolds:—And I object to it.

The Court:—Read the question.
(The last question was read.)

The Court:—I don't know there is any evidence he was reading from a book. The Court does not recall any evidence Mr. Reynolds was reading from any book. He may have been reading from some notes or something of that kind. The Court sustains the exception. You may redraft your question.

Q.—During the time you doctors were there Mr. Reynolds propounded questions to you with reference to whether or not you believed in the inhalation system, and what you thought of the inhalation system? A.—He may have asked that question. He presented some questions.

Q.—He asked you with reference to tubercular bacilli being in the human body, you were all there? A.—Yes, sir, we discussed that in a way.

Q.—And as a matter of fact at that time you discussed practically everything that has been testified here? A.—I couldn't say that. I know what I have testified. I haven't been in the court before. I don't know what has gone before, but I have said what I have said on this witness stand from my own knowledge of tuberculosis and have made up my mind without any coaching as to what I should say in answer to the questions which have been presented.

Q.—He asked you a question there, you doctors, whether or not the tongue could be depressed with a spoon for the purpose of examining the larynx? A.—I don't remember he asked me that direct question.

Q.—He may not have asked you, but the question was discussed? A.—You mean before I came to court?

Q.—Yes, prior to the time you came to court? A.—No, I don't think that question—

Q.—When you doctors were up there with Mr. Reynolds? A.—I don't remember that question was put to me at all before I came into court.

BRUNSON VS. FISHBEIN

223

Q.—Now, you doctors were told, were you not, that there had been some evidence that witnesses were going—ambulatory witnesses—to the office of the clinic here from their home for the purpose of taking treatment? A.—Yes, I understood that, I was told.

Q.—That question was asked, and you were told that testimony had been testified to here, that there was two trips a day? You so stated on your direct examination, did you not, Doctor? A.—In my testimony I said if the patient was making trips to a doctor's office the patient was doing something which is contrary to good treatment of active tuberculosis.

Q.—You said two trips a day to a doctor's office. Now, that was discussed, was it? A.—I was informed by some one that that is what happened, since I have been here. Yes, sir, I think I have heard that.

Q.—You were told, were you not, Doctor, of the testimony that was offered here by Dr. Brunson, what he testified to with reference to tuberculosis and his general theory of tuberculosis? A.—I was not told what he testified. I think probably two or three things that were said were presented to me by the attorney, but I got most of my information from reports of the testimony in the newspaper. I have read the paper every day since I have been here.

Q.—Now, you have been here since Monday, you say? A.—Sunday?

Q.—You are stopping at the Hilton? A.—Yes, sir.

Q.—Have you talked to Dr. Fishbein in reference to it? A.—Very little.

Q.—You have talked— A.—I have talked to him. I had breakfast with him this morning.

Q.—He told you how we were proceeding in the case and what was being done here, did he not? A.—He told me some things that had been said, yes, sir.

Q.—I didn't understand you? A.—I say he told me some thing that had transpired here.

Q.—Now, who brought you down here from Oklahoma? A.—I came down on the Rock Island.

Q.—At whose expense? A.—I don't know. I have not discussed my expense. I came at my own expense.

Q.—Are you to be reimbursed for your services in coming down here? A.—Not that I know of.

Q.—You have not discussed that at all? A.—I have not discussed that with anybody.

Q.—Who asked you to come down here. A.—Dr. Olin West of the American Medical Association.

Q.—What is his position with the A. M. A.? A.—I think his official position is Secretary of the American Medical Association.

Q.—When did he request you, Doctor? A.—Oh, I think I heard from him approximately two weeks ago.

Q.—Don't you expect to be reimbursed for the expenditure you're making coming down here? A.—No, I do not.

Q.—You do not? Now, Doctor, you stated, I believe, on direct examination that you had suffered from tuberculosis? A.—Yes, sir.

Q.—Did I understand you correctly? A.—Yes, sir.

Q.—And that was about twenty-five years ago? A.—Approximately that.

Q.—And you are now cured, Doctor? A.—I am clinically cured, yes, sir.

Q.—Now, clinically cured, what do you mean by that? A.—I am well in so far as any symptoms of tuberculosis are concerned, as far as I am able to determine.

Q.—It is inactive? A.—And apparently it is cured because I have been well for I expect twenty-three years anyway. I am not sure that I may not have live tubercle bacilli in my system.

Q.—You stated, I believe, that humans who did not have tuberculosis had tubercle bacilli in their systems, did you not? A.—No, I don't think I made that statement.

Q.—Did you make the statement that you were giving serums to babies and children? A.—No, I did not.

Q.—I have got that mixed up. Now, Doctor, you have been a tuberculosis specialist practically about thirty or thirty-five years? A.—I would say thirty-five years.

Q.—Now, from your experience and knowledge, what is the period of contagion in tuberculosis, Doctor—of incubation? A.—Oh, that is still a problematical question. I remember trying to answer that question. I might give my

experience. I was in Hamburger's Clinic in Vienna in 1909, and he was particularly interested at that time in trying to develop a tuberculin test for diagnosis, and he had an infant admitted to the clinic or hospital where he was observing children, with a negative tuberculin test. This infant was, while there, in contact, slight contact, with tuberculosis, and within about two and a half or three weeks the tuberculin test became positive. The incubation period though is still left more or less uncertain and may vary in different individuals.

Q.—And as a matter of fact— A.—Possibly two or three or four weeks.

Q.—As a matter of fact the medical world knows nothing about the period of incubation, isn't that a fact? A.—I do not think that is a fact.

Q.—You do not? Do you think they do know the period of incubation? A.—Approximately.

Q.—What is that period, now, Doctor? A.—Two to four weeks.

Q.—From two to four weeks after being segregated to the disease, or come in contact with it, or what? A.—Two to four weeks after coming in contact with tubercle bacilli the cells of the human organism become sensitive to tuberculin, showing there is reaction and the presence of the tubercle bacillus, and in my opinion when that takes place there is a disease effect from the tubercle bacillus, but the tubercle bacillus may become encapsulated and the individual affected may never manifest progressive pulmonary tuberculosis, or years later from that same infection tuberculosis may develop in clinical form. I think we know a great deal about it. There is a lot we do not know we would like to know.

Q.—You have no specific for the disease, have you? By you I mean the medical man? A.—I explained a while ago in my testimony.

Q.—I am asking you again? A.—We have no medical specific, but with our present knowledge of the treatment, rest approaches a specific, what might be termed a specific measure if it is properly applied at the proper time. And that means not only general rest of the body in bed, but local rest, which may be brought about by several different surgical means, including artificial pneumothorax, which means collapse of the lung by introduction of air. Then the other method is a little more artificial and of such a nature the air space cannot be so readily retraced, but justifiable, because if one measure of choice cannot be applied we resort to another, with the hope of bringing about an ultimate cure through the one principle of rest.

Q.—Rest is the whole thing in the treatment of tuberculosis? A.—I wouldn't say rest is the whole thing.

Q.—What else have you, then, if rest isn't? A.—We have dietetic and hygienic measures which are important, but not effective as a rule without rest.

Q.—State what they are? A.—Good food, three well balanced meals a day, and proper stuffing, as some doctors have done in the past, and proper hygienic measures, fresh air, light, sunshine, moving air.

Q.—That is all that the medical profession has, they depend on nature in the treatment of tuberculosis? A.—Often we need to give some attention to symptomatic—what we call symptomatic treatment, we give drugs to meet certain indications, perhaps for cough if we think it is indicated, to help patients to rest, to relieve pain, and sometimes tonic measures if the appetite is not good.

Q.—What do you do about the pus in the lungs, you let that be absorbed by the body and go into the various portions of the body? A.—With the treatment which I have described, the patient usually improves and with all of my effort to know what to do for people who have tuberculosis, I know nothing about what you call the pus, and I know of nothing except about improvement.

Q.—Isn't there formation of pus in the lungs? A.—Some times.

Q.—How do you eliminate that pus from the body, do you permit the body to absorb it or do you eliminate that from the body? A.—I depend on nature for elimination of the secretions that accumulate in the bronchial tree, that is the most natural thing in the world for a human being to eliminate through, the ciliated mucous membrane, with its effect on foreign material, and even the secretions which come from mucous membrane, and the reflex which gives rise to cough, when cough is needed to bring up the material, and that is the best method of elimination, because it is a response to nature without the undesirable

stimulation of expectorants. I purposely avoid giving cough mixtures which would stimulate cough, because I prefer my patient to let the lungs rest and cough only when necessary for elimination.

Q.—Then your statement, eliminating and everything, is you permit the pus to be taken care of by nature in the body? A.—I wonder if you happen to know that the tubercle bacillus can produce pus?

Q.—What is that? A.—I want to know if you know that the tubercle bacillus alone produces pus?

Q.—I haven't any idea. I am not a specialist, and I am asking you the question. A.—I apply all of the known and accepted methods of treatment, and so-called elimination of pus takes care of itself under those methods of treatment.

Q.—That is by absorption in the body? A.—And it is well known that the best results obtained in the treatment of tuberculosis are obtained through the principles which I have enumerated in my testimony.

Q.—Which is by absorption in the body? A.—In my testimony —

Q.—Don't those poisons from the pus pass into the liver, kidneys, heart, affect the heart and other vital organs of the body, is that unusual in tubercular cases? A.—I don't know anything about that. I never have seen the effects of it, either clinically or post mortem.

Q.—You don't know whether or not tuberculars are usually and ordinarily sufferers, that is, tuberculars of some length of standing, from kidney trouble, liver trouble, and poisons from the lungs go into the various organs of the body, isn't that a fact? A.—Occasionally we see tuberculosis of the kidney; otherwise the kidney seems to remain quite free from disease.

Q.—Does the blood stream ever take up any of these poisons from the pus formed in the lungs and take it into the stomach by swallowing? A.—The blood does absorb poisons or toxins, but in tuberculosis the toxins that are absorbed are manufactured by the tubercle bacillus.

Q.—That goes in the blood? A.—We think that causes the fever we have in tuberculosis.

Q.—It doesn't come, in your opinion, from the absorption of the pus by the various portions of the body, taken in the stomach, as so many do not expectorate? A.—In my opinion it does not come that way. The absorption of the toxins from the tubercle bacillus is chiefly from the closed lesions. After the tubercle ulcerates into the bronchus, the toxic material is eliminated through the bronchial tree and the continuation of the symptoms of toxemia is probably due to tubercles yet unruptured, and the so-called mixed infection or the presence of other bacteria is found because they are normally present in the respiratory tract. We have to remember that the lining membrane of the bronchial tubes and even the air cells is external, from an atmospheric standpoint, and exposed to all of the bacteria and all of the dust in the atmosphere, and germs are constantly in the mouth, nose, throat and even in the trachea, and to some extent in the bronchial tree, and if they are found in purulent sputum that finding constitutes no evidence that those bacteria are the cause of the pus or the cause of the symptoms which arise in the course of tuberculosis, that is external, and probably no absorption from the presence of them.

Q.—Probably no absorption. What becomes of the pus, then, from the lungs? A.—It is eliminated through the bronchial tubes and out through the larynx.

Q.—And that that is swallowed by the patients, as is usually done, when there is no means of causing expectoration? A.—Sputum is sometimes swallowed, and we teach patients who have reached the age of understanding — we don't often see young children with sputum from tuberculosis — we teach them not to swallow sputum because we think it is not a good thing. We teach them not to cough more than necessary, because coughing might tend to exaggerate the trouble in the lungs and help to localize trouble in the larynx.

Q.—If you teach them not to cough, much of the phlegm stays in the lungs? A.—No.

Q.—What becomes of it? A.—It travels along the bronchial tree and finally there is a reflex impulse through the irritation of the nerve end, as in the mucous membrane, which prompts the patient to eliminate by coughing. I teach my patients to cough as moderately as possible in order not to agitate the diseased lung.

Q.—That is what you physicians depend on is nature? A.—What?

Q.—You depend on nature to eliminate the pus from the body? A.—Nature does that better than anything I know of.

Q.—Now, Doctor, in the examination of sputum under the microscope, did it or not show a preponderance of pus germs? A.—In answer to that question, I would have to explain, because every case of tuberculosis is an individual problem for the physician, and every specimen of sputum has its individual characteristics, even though tubercle bacilli are present, sometimes there are many different kinds of bacteria, sometimes there are only a few, and really every specimen of sputum from any one given case varies under the microscope. There may be more tubercle bacilli today than tomorrow, they may be present today and absent tomorrow, there may be more of the other bacteria today than tomorrow, and those bacteria may come from the mouth or nose or bronchial tree and not from the tubercle.

Q.—If there is a running sore on the hand or on any part of the body, on the exterior, do you clean the sore off, do you take the pus off, wash it and put a disinfectant on it, or do you leave it to nature to eliminate the pus and heal the sore? A.—As a rule, drainage of any superficial inflammatory condition, especially when pus is present, is considered of value; as long as we get that through the bronchial tree, there is already a facility for that sort of thing.

Q.—You clean off an exterior running sore, eliminate the pus? A.—Nature tends to eliminate pus even on a superficial sore.

Q.—Then I understand you don't clean it off? A.—I use my judgment in treating conditions like that, keep them clean and use whatever I think is best for that, I do the same way in treating the lungs.

Q.—You do keep them clean. Now, an abscess on the body, must that be opened so as to get the pus out and let it run out? A.—That is considered the best practice at the proper time; if an abscess forms, ordinarily it is opened because that facilitates healing.

Q.—You don't depend on nature to eliminate the pus, then, you think an abscess should be opened and pus removed? A.—If, through the process of nature and the response of the tissues the pus localizes, the inflammatory condition localizes and pus forms, we think it is good practice to lance such an abscess and allow the pus to drain out. When a tubercle opens into the bronchus we have similar drainage of the dead tissue, and possibly the sputum will show tubercle bacilli and other bacteria; but the sputum would show the other bacteria before the tubercle opened.

Q.—Now, I will return to a question I asked you a while ago with reference to depressing the tongue to see the larynx, to see if it is infected. You said you could not do that, it could not be done, did you not, on your direct examination? A.—I did not say the tongue could not be depressed. I said with all possible depression of the tongue the larynx could not be inspected without the aid of additional means.

Q.—I will ask you if you have ever done that, if you have ever tried that? A.—I have looked into the throat, of course, but I could not see the larynx by depressing the tongue.

Q.—Then you have never tried it? A.—I tried to see everything I could.

Q.—I asked you this, Doctor, could you by depressing the tongue see the larynx? A.—When I was a medical student I was taught to see the larynx.

Q.—You still have not answered my question. I asked did you ever do that, depress the tongue to see the larynx? A.—I depressed the tongue and looked for everything that the human eye could discover by such a means and I never yet have seen the tubercles down in the larynx by such a means.

Q.—And you say then from that experience it could not be done and that is not possible? A.—Yes, sir.

Q.—And that no one else can do it if you have not done it? A.—I would not speak for everybody else.

Q.—That is what you are saying, Doctor.

The Court:—Counsel will not argue with the witness.

A.—My eye should have about the same scope of vision under such circumstances and conditions as anybody else's.

Q.—Now you spoke of the inhalation method of treatment in response to Mr. Reynolds' question here. Have you ever seen the method of treatment that he was speaking of of inhalation? A.—I have seen various methods of inhalation but I have not seen the method which is under discussion in this Court.

By Mr. Reynolds: RE-DIRECT EXAMINATION

Q.—Doctor, in the case of a running sore or abscess on the exterior of the human body is any treatment of an oily substance such as has been described here indicated for the elimination of pus? A.—Not that I know of.

Q.—In the case of inhalation of such an oily substance is it or is it not true, Doctor, that that oily substance itself may cause an irritation which increases expectoration? A.—I discussed that in my testimony. I think that is true, it might do that.

Q.—And, Doctor, is it physically possible for the human eye to look around the corner? A.—No, not at all.

Q.—Doctor, tell us where the larynx is located in the human body. A.—I think for those who are not familiar with anatomy I might say that the larynx can be located by the so-called Adam's apple, and it is a small rectangular organ, made up of cartilages and muscles and contains the vocal cords and it is right behind my finger (indicating). My finger is parallel to my vocal cords. It is immediately in front of the tube which leads to the stomach and immediately behind the breast bone, and normally in the center running vertically from the base of the tongue or bottom of the pharynx to its bifurcation or where the windpipe or trachea divides into what we call the primary bronchi, two in number, one leading to the lung, that is, to one lung, and one to the other.

Q.—Doctor, is it not common knowledge among the medical profession you cannot see the vocal cords with the naked eye, merely by looking into the mouth? A.—That is so.

Witness excused.

The following proceedings were had out of the hearing of the jury: Mr. Quaid:—The plaintiff at this time desires to object to the testimony of Dr. Watson, it appearing that the rule was called for at 9:30 Monday morning at the announcement of ready for trial, and the evidence just developed by the defendant through one of its witnesses, Dr. Moorman, is that Dr. Moorman, Dr. Randolph and Dr. Watson met together with the attorneys of the defendant and discussed the testimony in the case and also discussed some of the testimony to be given by such witnesses on the witness stand, same being in violation of the rule invoked in this Court.

Mr. Reynolds:—Your Honor, in the first place it was our understanding that your ruling at that time was that these doctors did not have to be brought in and put under the rule; they have not been in the Court. That has been nothing like that since. We will bring the other doctors, call them over from the hotel, if it is the Court's desire. We understood that as not necessary and counsel also had a list of doctors and they were brought in.

The Court:—The Court announced at the time the rule was invoked that all witnesses then present and in attendance on the Court would be sworn and placed under the rule and that the Court would rely on counsel for the plaintiff and defendant respectively to inform the Court on the arrival at the Court of witnesses they expected to use and they would then be called before the Court and placed under the rule. The Court does not understand that there has been any violation of that ruling by the Court.

Mr. Brown:—I was present at the conference when we consulted about matters before we were called into Court.

Mr. Reynolds:—It has certainly been a misunderstanding with us.

The Court:—In view of the question raised by counsel for the plaintiff, the Court will say that all witnesses you expect to use will be kept out of the court room this afternoon. All witnesses on both sides will be notified to be in attendance on the Court tomorrow morning and sworn and placed under the rule unless there is agreement between counsel to waive it. There may be a difference of opinion on it and the Court will make it arbitrary.

TESTIMONY OF DR. SAMUEL H. WATSON: DIRECT EXAMINATION

By Mr. Reynolds:

Samuel H. Watson, Tucson, Ariz., a physician, stated that he had been at Tucson since 1911. He is associated with the Tucson Clinic, a group of physicians to practice medicine. He graduated from Rush Medical College in Chicago in 1899, then went to Iowa and practiced medicine for twelve years in general practice. Then he went to Tucson, as he had tuberculosis. After he recovered his health he decided to limit his work to internal medicine and, living in a health resort like that, a great part of the work is disease of the chest in internal medicine. Nearly every summer he takes at least two months off and makes it his business to call on other men doing work with tuberculosis and in sanatoriums. He is past president of the county medical association, member and past president of the state medical association; member and past president of the Arizona Anti-Tuberculosis Association; member and past director of the National Tuberculosis Association; member of the American Sanatorium Association; member of the American Medical Association, the American College of Physicians, the American Academy of Tuberculosis and the American College

of Tuberculosis Physicians, and certified to the American Board of Internal Medicine in internal medicine. He has written articles for publication on tuberculosis in various journals.

Q.—Dr. Watson, are you familiar with the literature and the reports regarding various remedies applied for the use and treatment of tuberculosis for the past decade or so? A.—I am.

Q.—What has been the extent of your study in that regard? A.—I do not know just what you mean by that question.

Q.—I was just trying to get at, Doctor, what journals and reports, etc., you rely on for your information. A.—I try to read the current medical journals that publish articles on the work of the chest, particularly tuberculosis. As I say, I visit other men doing chest work and try to learn what they are doing.

Q.—Have you been doing all that since you began specializing in this field? A.—I have.

Q.—Now, Doctor, is a theory that a treatment for tuberculosis should be aimed at the secondary infection anything new or novel in medical science? A.—No, sir.

Q.—What is the history of that? A.—The history of that is that tuberculosis—we are talking about pulmonary tuberculosis? A.—Yes. A.—It is a primary disease of the lungs and until that disease itself—it is the nature of the tuberculosis to ulcerate, to eat, until that disease ulcerates into the bronchial tube, where it is contaminated with the organisms we all always have present; there is no such thing as secondary infection.

Q.—Is the advocacy of the use of mineral oil and volatile terpene-like substances anything new or novel in theory regarding the treatment of pulmonary tuberculosis? A.—No, sir.

Q.—For how long has that been advocated or when was it advocated in a general way? A.—For a long time. I could not state the number of years, but many, many years ago it was suggested and it was tried and then discarded and then before we realized that rest was a cure in tuberculosis it was tried again, I would say, perhaps, the early part of this century, but since then it has been discarded.

Q.—Now, Doctor, assume a substance which is an oily fluid containing approximately 95 per cent mineral oil and 5 per cent volatile terpene-like substances such as eucalyptus, menthol, sometimes known as mint camphor, and other terpene-like substances such as oil of pine and thymol, can you tell us whether or not such a liquid is an irritant to lung tissues? A.—It could well be.

Q.—Will you explain why, Doctor? A.—Because we have found that oils frequently produce inflammation of the lung, and the inhalation of such a substance with the body of it 95 per cent oil could readily do that.

Q.—Now, Doctor, will you explain to us just exactly how, what happens? A.—When one is infected by the tubercle bacilli nature mobilizes her forces and tries to surround the bacilli and protect the body. That makes little nodules, little spheres with the tubercle bacilli in the center and the cells around, trying to limit the disease.

Q.—What happens then, if anything? A.—If nature wins the fight, of course the tubercle bacilli are encapsulated and the cell tissues are scarred, making scar tissues, and healing takes place.

Q.—Now, Doctor, is it your opinion that in the treatment of pulmonary tuberculosis the treatment should be aimed at the secondary infection? A.—Not at all.

Q.—Why not? A.—Because what kills the patient is the most important thing present and that is the original infection of the tubercle bacilli.

Q.—Now, Doctor, what is the accepted treatment for pulmonary tuberculosis now? A.—Rest, comprising general and local rest.

Q.—And is there a clinical cure for pulmonary tuberculosis? A.—Absolutely, yes.

Q.—Is there a bacteriologic cure? A.—That is a question.

Q.—Has there ever been any indication that the administration of any drug would affect the bacteriologic cure? A.—Never.

Q.—Or any oil? A.—Never.

Q.—Doctor, as far as your own case is concerned you experienced a clinical cure, did you? A.—I did.

Q.—How long ago was that? A.—I started my cure about twenty-eight years ago.

Q.—Now, Dr. Watson, in connection with pulmonary tuberculosis I will ask you if in your opinion this statement is true or false: "It is the pus germ that does the most harm?" A.—No.

Q.—Is it your opinion that this statement is true: There is no patient with tuberculosis that does not have a cough? A.—No, sir.

Q.—Why not? A.—I would say the most frequent early symptoms of tuberculosis was fatigue rather than cough.

Q.—Is this statement true: There is only one type of tuberculosis? A.—No, sir.

Q.—Why it is untrue? A.—Because there are several types.

Q.—What are they, what are a few of them? A.—Might have a chronic bronchial tuberculosis, might have a miliary tuberculosis, might have a fibroid ulcerative tuberculosis. We are talking about pulmonary tuberculosis.

Q.—Doctor, what do you understand by the term alveoli? A.—Alveoli, they are the ultimate air cells of the lung.

Q.—Is this statement true with regard to them: The air cells of the lung are closed on inspiration? A.—No, sir.

Q.—Is this statement true: The air cells of the lung are open on expiration? A.—No, sir.

Q.—What is the truth in that respect? A.—It is just the opposite.

Q.—Doctor, is it true that the larynx opens into the esophagus? A.—No, sir.

Q.—Is it true the pharynx opens into the trachea? A.—No, sir. The larynx is a part of the respiratory system and opens into the trachea, or windpipe. At the bottom of the pharynx comes the digestive tract, and at the top of the respiratory tract there is a little trap door that when we swallow closes up the opening in it.

Q.—In speaking of it then just the reverse is true, is that correct? A.—Correct.

Q.—Doctor, will you tell us the difference between subjective and objective symptoms? A.—Well, subjective symptoms would be the symptoms that the patient would tell me about; objective symptoms would be the symptoms that I myself could find.

Q.—In the case of attempting to diagnose tuberculosis, pulmonary tuberculosis, would the things you learn with the stethoscope be a subjective symptom? A.—That would be an objective symptom?

Q.—And would the things that might be interpreted from x-rays be a subjective symptom? A.—No, sir, that would be objective too.

Q.—Would whatever might be determined from sputum tests be subjective? A.—No, sir, that would be objective.

Q.—Now, Doctor, in your opinion is it physically possible to see nodules caused by tuberculosis of the larynx by the simple use of a tongue depressor? A.—No, sir.

Q.—Why not? A.—It is a long ways down to the lung, and even if you could go much farther down you could not see the tubercles in the lung because the windpipe simply goes into the bronchial tubes. It is impossible.

Q.—Now, Dr. Watson, is it or is it not true that pulmonary tuberculosis may be accompanied by a temperature, body temperature, which is above normal? A.—Yes, sir.

Q.—It is true that it may be accompanied by rales in the chest region? A.—Yes, sir.

Q.—And is it true that it may be accompanied by an abnormal pulse? A.—Yes, sir.

Q.—And is it true that it may be accompanied by a reduced blood pressure? A.—Yes, sir.

Q.—Now, Doctor, supposing a patient had all four of those symptoms, does that necessarily mean that he has pulmonary tuberculosis? A.—Not at all.

Q.—How many other diseases can you have, offhand, that might give the same indications, the same symptoms I mean?

A.—Offhand I can't say how many, but there would be any number of diseases that might produce those various symptoms.

Q.—Doctor, in making a diagnosis for pulmonary tuberculosis what, in addition to determining those symptoms, is customarily done? A.—Of course the absolute symptom is finding the tubercle bacillus in the sputum.

Q.—And that is done how? A.—That is done by collecting sputum that the patient raises and having a competent laboratory technician examine it, and of course an x-ray; often we are pretty sure from the history and of stethoscopic examination, but that is not positive; it has to be checked.

Q.—Doctor, in the use of the stethoscope, will you explain to us just what it is, what is a stethoscope? A.—A stethoscope is an instrument for enabling the examiner to concentrate,

collect sounds, and better than he can with his own ears, and is commonly used by all physicians who examine the chest.

Q.—Of what does it consist, just describe it? A.—It has two ear pieces that fit in your ears, and they come together in a sort of bell shaped arrangement that you can put on the chest and localize the sounds.

Q.—Is there any amplifying mechanism in that at all? A.—Not an ordinary stethoscope.

Q.—Just hollow all the way through? A.—That is right.

Q.—Is it essential in using a stethoscope that a man have acute hearing? A.—Yes, sir.

Q.—Now, Dr. Watson, have you a knowledge as to whether or not inhalation of oils or substances containing terpene-like substances have been tried in the treatment of tuberculosis? A.—Yes, sir.

Q.—And, Doctor, assume a treatment for pulmonary tuberculosis consisting of an atomizer, to which is attached an oxygen tank, a pressure gage and the oxygen tank is set between 35 and 40 pounds, that in the atomizer is contained an oily substance or solution composed of 95 per cent mineral oil and 5 per cent volatile terpene-like substances, including eucalyptus and menthol, and also terpene-like substances which have oil of pine and thymol; that the mechanism of administration is to place the tip of the atomizer in the mouth of the patient, and the patient taking ten inhalations twice daily, and each time the oxygen being forced through it produces a vapor from that substance; have you or have you not an opinion as to whether such a treatment might or could be efficacious as to treatment for pulmonary tuberculosis? A.—I have such an opinion.

Q.—What is your opinion, Doctor? A.—I do not see how it could be efficacious from the standpoint of medication, and I can see why it might be harmful because of the inhalations, if I may explain that, by making the lungs exercise more.

Q.—What do you mean? What is there that makes them exercise more? A.—Well, deep inhalations.

Q.—Suppose that treatment were given as an ambulatory treatment or—in other words, the patient coming to and from the office; with that fact in mind have you an opinion as to whether or not such a treatment might or could be dangerous to the patient suffering from pulmonary tuberculosis? A.—I have.

Q.—And what is your opinion? A.—It would be harmful.

Q.—Will you state why? A.—Because the one healing remedy we have for pulmonary tuberculosis is rest. Anything that makes the patient exercise gives more exercise to the lungs, and so it would be harmful.

Q.—Now, Doctor, is there any indication that any of that substance would penetrate the tissues in the lungs? A.—None.

Q.—And unless it did penetrate could it have any therapeutic effect? A.—None.

Q.—In regard to tuberculosis, Doctor, is it or is it not a fact that all persons have in their body tuberculosis or tubercle bacilli? A.—All persons have?

Q.—Yes, all persons have? A.—No, all persons do not have.

Mr. Reynolds: That is all. You may examine.

ON CROSS EXAMINATION:

Questions by Mr. Quaid:

Q.—Dr. Watson, when did you get to El Paso this trip? A.—Sunday.

Q.—You know Dr. Moorman? A.—Yes, sir.

Q.—And you know Dr. Randolph? A.—Randolph, I know him.

Q.—You have talked over this case with those doctors, have you not? A.—Well, we met with the attorneys on Sunday afternoon, I think it was, and those doctors were present.

Q.—Who else have you talked to since Sunday? A.—No one except the attorneys and these doctors. Dr. Hruby, I think you were trying to ask me about.

Q.—Who else have you talked to? I don't believe I understood your answer. Who else have you talked to since Sunday? A.—Who else have I talked to since Sunday?

Q.—Yes, sir. A.—No one except the attorneys and these doctors.

Q.—Attorneys, and what doctors? A.—Dr. Randolph, Dr. Hruby, Dr. Moorman and Dr. Corper.

Q.—Now, were the attorneys present when you doctors were present? A.—Yes, sir.

Q.—And that is since Sunday, isn't it? A.—Well, we met at a conference on Sunday afternoon. Since that time in trying to pass the time, spend the time, we doctors have been together, and naturally we have been talking about tuberculosis, but not about this particular trial, because we did not know about it.

Q.—When you were together did you talk about this case? A.—We did not know anything about this case. We talked about the general subject of tuberculosis.

Q.—Did you talk about inhalation treatment? A.—Yes, sir.

Q.—What else did you talk about?

Mr. Reynolds:—I object to that, your Honor.
The Court:—The Court will sustain the objection.

Q.—Have you ever tried the inhalation treatment yourself? A.—I never have.

Q.—You never have? A.—No, sir.

Q.—Have you ever seen a patient that it was tried on? A.—No, sir, I never have.

Q.—Doctor, could you make an absolute diagnosis of tuberculosis on a patient with a stethoscope? A.—No, sir.

Q.—You could not? A.—No, sir.

Q.—What else would you have to have? A.—Well, I would want a careful history first, then I would use my stethoscope, and would want an x-ray, and would want a sputum examination.

Q.—Do you always do that with every patient? A.—Yes, sir, every patient I suspect tuberculosis on.

Q.—That is what I mean. A.—Yes, sir.

Q.—You do not treat any patients without having a stethoscopic examination, a sputum test, and what else? A.—X-ray and history.

Q.—X-ray and history? A.—Correct.

Q.—You do not treat any patients without having those four things? A.—That is for tuberculosis. Correct.

Q.—That is what I am talking about. Doctor, isn't eucalyptus oil and menthol a pulmonary antiseptic? A.—Antiseptic?

Q.—Antiseptic? A.—No, sir, not in my opinion.

Q.—It is not? A.—Not in my opinion.

Q.—Not an antiseptic? A.—A pulmonary antiseptic?

Q.—Yes? A.—No, sir, not in my opinion.

Q.—Is it a bronchial antiseptic? A.—Not in my opinion.

Q.—Now, Doctor, you said something about the exercise of the lungs. What do you mean by that, do you mean coughing?

A.—Well, coughing would be one form of exercise. Of course, I mean anything that makes your lungs breathe in or out, either deeper or faster, anything that would aggravate that.

Q.—Cough would be one thing, would it not? A.—A cough would be one thing.

Q.—Have you ever experienced in your practice a situation where your theory was that a certain treatment would not be beneficial, but on actual trial of the treatment the patient improved and was benefited?

Mr. Reynolds:—There is one matter we would like to take up with the jury before court adjourns, but it should be done out of the presence of the jury.

The Court:—Gentlemen of the jury, you will be excused until 9:30 tomorrow morning.

The jury thereupon retired from the court room at 5 p. m., whereupon the following proceedings were had:

Mr. Reynolds:—Your Honor, in regard to proceeding with further testimony there is one witness who is ill and unable to be in court. His testimony is to identify an additional sample of Dr. Brunson's remedy and trace it to a chemist so that we may have a further analysis, not having had any disclosure so far as to what this remedy consists of; and under the circumstances, unless counsel will agree that the sample taken by Mr. McCoy from Mr. Emmett Denton is a true sample we would like to take his deposition tonight, if we may. It will only take a few questions, but he is confined to his bed.

Mr. Quaid:—We would agree to take his deposition tonight.

Mr. Reynolds:—All right, we will make arrangements.

The Court:—With that understanding the deposition may be taken tonight.

Thursday, June 1

DEPOSITION OF FRANK P. O'HARA, DIRECT EXAMINATION
Taken in the county of Erie, N. Y., at Rocky Crest Sanitarium, near Olean, N. Y., March 13, 1939.

Questions by Mr. Burke:

Frank P. O'Hara stated that he is confined in Rocky Crest Sanitarium near Olean, N. Y. He had a conversation June 15, 1938, with Dr. Brunson that pertained to his case, in Dr. Brunson's office.

Q.—And what was said by you and what was said by him? A.—I told Dr. Brunson that I would like to break the monotony of being in El Paso by taking a short trip into the interior of Mexico for three or four days but that at the same time I didn't wish to break the treatments and wondered if it would be possible for me to make this trip, taking some of the medicine with me, in order to continue the treatment while I was away. To this he answered that it would be, and that he would have Mrs. Brunson loan me her atomizer to take along with me.

Q.—Did Dr. Brunson at that time or on that day give you a liquid of any kind? A.—Yes sir. He gave me what he said was Mrs. Brunson's atomizer containing his medicine and explained to me how to use it and told me that he was giving me that medicine for nothing, when Fishbein would pay a thousand dollars to get it.

Q.—Did he state at that time whether or not the liquid or medicine which he gave you in the atomizer was the same as the medicine which he had been using on you twice a day from the time you came to El Paso? A.—He said this is the same medicine as I have been getting, except I would not get the same results from it, inasmuch as there was a difference between taking the formula from an oxygen tank and taking it from a hand atomizer.

Q.—What did you do with the liquid which he gave you at that time? A.—I transferred the liquid into a 1 ounce bottle and kept it in my possession at all times until it was finally deposited in a safe deposit vault in the Northern Trust Safe Deposit Company's vaults on La Salle Street in Chicago, Illinois.

Q.—Did you have a conversation with the doctor at that time? (Referring to afternoon of June 24.) A.—I did.

Q.—What did you say to him and what did he say to you? A.—Well, he had all this equipment with him, and he told me that he was giving me a month's supply of his medicine, at \$60, and that he would allow me a credit of \$30 for the unused one-half month for which I had previously paid him. He then told me that the equipment came to \$24.89, so I gave him the additional \$4.89, together with the \$30 for the medicine. As I had not returned Mrs. Brunson's atomizer, I told both Dr. Brunson and Mrs. Brunson I would bring it to their apartment that evening. That evening I returned the atomizer, and Dr. Brunson asked me for the first time since I had arrived in El Paso for my home street address. I gave it to him, and I told me he would like to hear from me from time to time how I was doing and to give him a complete report each month as I continued the medicine. I then left the apartment.

Q.—Describe the equipment that you have mentioned which Dr. Brunson gave to you? A.—The equipment turned over to me by Dr. Brunson consisted of two bottles of his formula, and so labeled, one meter to be attached to the oxygen tank, one piece of hose, one shut-off cock, one atomizer jar, one atomizer nozzle.

Q.—Did Dr. Brunson discuss with you in any way at or about that time the kind of oxygen that you were to endeavor to get in Chicago? A.—No. He just said medical oxygen; that I could buy it from any drug store.

Q.—In the course of your conversation with Dr. Brunson on June 24, 1938, did he state to you whether or not the liquid which he gave to you in the two bottles was or was not the same liquid which he had been using in giving the treatment to you? A.—He told me that it was the same liquid.

Q.—Did he give you the two bottles personally? A.—He did.

Q.—What did you do with the two bottles of liquid which you received from Dr. Brunson on June 24, 1938? A.—Took them in my traveling bag and brought them back with me to Chicago.

Q.—How soon after the doctor gave you the two bottles of medicine did you leave El Paso? A.—He gave them to me the afternoon of June 24, 1938, and I left El Paso at 4:15 in the morning of the 25th of June.

Q.—What form of transportation did you use for the trip between El Paso and Chicago? A.—American Air Lines.

Mr. O'Hara then told how he transferred the medicine to Mr. Burke and the chemists.

Q.—State what if anything was said and done there at that time in the office of Dr. Leech. A.—Mr. Burke asked me to explain to Dr. Leech the various items that I had brought to his office, which I did; he then called in Dr. Schoeffel and had me tell him the same thing. Dr. Schoeffel then transferred approximately one half of the contents of the 1 ounce bottle into a glass stoppered bottle, to which he attached a sticker and

wrote thereon in his own handwriting the capital letter A, together with his initials. (Mr. O'Hara then described the preparation of the remaining samples.)

Q.—Mr. O'Hara, previous to going to El Paso, Texas, and meeting Dr. Brunson there, what had been your business or occupation? A.—I was in the radio manufacturing business.

Q.—How long had you been in that business? A.—With various concerns for about ten years.

Q.—Will you tell us, Mr. O'Hara, the names of the concerns with whom you were associated during that period? A.—McMillan Radio Corporation, Clago Radio Corporation, Capitol Radio Corporation, Echophone Radio Corporation and Corona Radio & Television Corporation, and Addison Radio & Electric Corporation.

Q.—What was the nature of your connection with these various radio concerns, Mr. O'Hara? A.—Either purchasing agent, sales manager, production manager or general manager.

Q.—Are you a family man or a single man? A.—Family man.

Q.—You have some children? A.—I have two children, a boy and a girl.

Q.—Is your wife living? A.—Yes, sir.

Mr. Quaid:—I want to first introduce some of the cross interrogatories propounded to the same witness, that is, Frank P. O'Hara.

Third Cross Interrogatory.—If you answer the foregoing question in the affirmative, then please state the names and addresses of all physicians who diagnosed your case prior to May 9, 1938, stating the nature of their diagnosis with reference to what disease you are suffering from, if any.

Mr. Harrell:—If the Court please, I am objecting to that interrogatory for the reason that we haven't attempted in this to bring out anything regarding Mr. O'Hara's treatment by Dr. Brunson, we have simply introduced here testimony by deposition to show the transfer of the liquid, the formula that he obtained from Dr. Brunson, and for no other purpose.

The Court:—Read the question, please. (Question read.) Sustain the objection.

Mr. Quaid:—In the direct, we will offer the following: (Referring to direct examination of same witness.)

Q.—In the early part of May 1938 did you meet and talk to Dr. Asa Brunson of El Paso, Texas? A.—On May 9, 1938, I called on Dr. Brunson at about 10:20 in the morning for the purpose of consulting him with reference to placing myself under his care for the treatment of tuberculosis.

Q.—What did you say to him and what did he say to you at that time? A.—I told him that I had heard that he had a treatment for tuberculosis and that I came to see him about it. He took me into his private office and for something over an hour gave me a discourse on his ability to cure the disease, and the number of people that had called on him in worse shape than I was and were cured in a very short time. He asked me no history in regard to my case but at about 11:30 in the morning asked me to remove my shirt and went over me with a stethoscope, and told me that yes, I had tuberculosis, but he was sure that his treatment would help me; that the treatment consisted of an inhalation process that was administered twice a day and that it would cost me \$60 for one month, payable in advance. So I paid him the \$60, getting a receipt for it, and was given my first treatment by a woman in the office who apparently acted as his assistant, and at the close of the treatment I was told to come back at 3:30 that afternoon for another treatment.

Q.—When did you next go to the office of Dr. Brunson? A.—On May 10, which was the following day, and I received the same treatment as I did on May 9. May 9 was Monday.

Q.—That is, do I understand you correctly, that you went twice to the office of Dr. Brunson in El Paso on the 10th of May? A.—Twice on each day and every day that I was there, except Sundays.

Q.—Other than the treatment twice each day which you have mentioned, when did you next talk to Dr. Asa Brunson? A.—Other than having the Doctor greet me in the morning and afternoon at the times that he was there with "How are you today? You are surely looking fine" I did not have any conversation with Dr. Brunson until May 18, at which time he gave the usual greeting that I was looking fine to which I answered that I could not notice any improvement. He replied "Do not worry. You are coming fine, your color is much better." That was on the 18th of May.

Q.—When did you next see and talk to Dr. Brunson? A.—On the morning of the 19th of May, 1938, the doctor gave me the treatment, as Mrs. Brunson, who had replaced the attendant that the Doctor had when I first started taking treatments, was busy painting the cabinet; I was greeted with the usual con-

versation of "How are you this morning? You are looking fine." I replied that my pulse seemed rather fast. So he felt of it and said he would give me something for it when I came back in the afternoon. At 3:30 that afternoon I took the other treatment and he gave me a small box of pills; he said they were strychnine and to take one before each meal. Inasmuch as I did not have the proper amount of confidence in the Doctor, I did not take the pills. I was charged 20 cents for them, as he claimed to have got them himself from the drug store, and that he always passed his discount on to his patients.

Q.—When did you next see Dr. Brunson? A.—On the morning of May 20, 1938.

Q.—Did you have a conversation with him at that time? A.—He gave me the treatment that morning.

Q.—Did you have a conversation with him at that time? A.—He asked me if I had read the May copy of *Ken*.

Q.—Well, you did have a conversation with him then? A.—Yes.

Q.—Tell us what you said to him and what he said to you? A.—He asked me if I had read the May copy of *Ken*, in which there was an article—

Mr. Harrell:—I object to whether he read the May copy of *Ken*; that has nothing to do with the issues here. As I said before, the only reason why we put in these questions and are making this proof is to connect up this medicine, that is, to show the delivery of the medicine. The promise I made to the Court yesterday was we would connect up this medicine and trace it into Dr. Schoeffel's hands. Now, we have read portions of this deposition for that purpose, we made that showing, and read them for that purpose and no other.

Mr. Quaid:—This is direct examination; they themselves asked the witness.

The Court:—The Court can pass on it better when he sees the answer. (Handed to Court.) The Court sustains the exception.

Mr. Quaid:—Note our exception.

Q.—When did you next see Dr. Brunson? A.—On May 21, 1938, Dr. Brunson gave both the morning and afternoon treatment, and the conversation was rather general, and nothing pertaining to my physical condition or to the treatment was mentioned.

Q.—When did you next see Dr. Brunson? A.—On the morning of May 24, 1938.

Q.—Well, did you have a conversation with him at that time? A.—Yes.

Q.—What did he say to you and what did you say to him? A.—He told me that I was responding to the treatment very well and that it would only be a comparatively short time before I would be able to go back to Chicago a well man. Mrs. Brunson then gave me the treatment.

Q.—When did you next see Dr. Brunson? A.—I saw him in his apartment that evening about 7 o'clock.

Q.—Where was his apartment located? A.—In the Cortez Hotel.

Q.—When did you next see Dr. Brunson? A.—On the morning of May 26, 1938, after Mrs. Brunson had given me the treatment; and when I was leaving the office, the Doctor came in and remarked how well I was looking, and asked what kind of a night I had? I told him a very good one. I asked him if he would recommend a good laxative. He suggested Fleet's Phospho-Soda and fixed me some, which I took in his office. He asked me if I was weighed lately. I told him no. He told me I looked much heavier, but when he put me on the scales I was 1 pound lighter than I was about two weeks before.

Q.—Now, when did you next see Dr. Brunson? A.—In the afternoon of May 26, 1938.

Q.—Did you have a conversation with him at that time? A.—I did.

Q.—What was said by him and what was said by you? A.—As I was leaving the office, the doctor came from his office, slapped me on the back and said I was coming along just fine and asked me if I was coughing as much as I was when I first arrived. To this I answered that I was not coughing as much.

Q.—When did you next see Dr. Brunson? A.—In the afternoon of the same day.

Q.—Was that in his office? A.—In his office.

Q.—Did you have a conversation with him at that time? A.—I did.

Q.—What did you say to him and what did he say to you? A.—When I got there he was alone in the office and had me come in and asked me to strip to the waist. He spent about ten minutes going over my chest and back with a stethoscope. He then told me that I was well on the way to becoming a well man; that both of my lungs were in very good shape; that

BRUNSON VS. FISHBEIN

229

he was unable to locate a single rale in either lung. He then told me that at sixty days, or possibly less, I could leave him as well a man as I had ever been, and that I would be able to live in any climate and do any kind of work, no matter how hard. From there the conversation drifted to some of the patients that he had cured. He told me there was not a single T. B. doctor in El Paso that he had not taken patients from that they were unable to cure, and that he, Dr. Brunson, cured them.

Q.—Had Dr. Brunson directed you, up to this time, to have any x-ray pictures made in El Paso, Texas? A.—He did not; in fact, he told me that they were absolutely unnecessary; that he could tell much more with the stethoscope than most doctors could with all kinds of x-ray pictures.

Q.—Will you continue, please, your conversation with Dr. Brunson concerning the x-rays which you had brought with you to El Paso, Texas? A.—When I told him that I still had them, he said that he would drop into my room in the Hotel Cortez, where his apartment was also located, on the night of June 2 and look at them. I waited until 7:40 p. m. in my room, and as he did not come I called him and said that if he wanted me that I would bring the x-rays to his apartment, and at the same time return the books Mrs. Brunson had previously loaned, and he took the x-rays when I arrived at his apartment and appeared to study them for a short while, and said that from what he could see they showed more trouble in the left than in the right lung.

Q.—What was said by you and what was said by him? A.—He asked me if he could keep the plates for a few days, that he would like to take them to a laboratory where he could go over them more carefully. The rest of the evening was spent in general conversation until about 9:30, at which time the doctor went out for some ice cream.

Q.—Did you read the letter which she handed to you in the presence of Dr. Brunson?

Mr. Harrell:—I am objecting to reading any letters she handed to him. The letter is not identified and certainly couldn't be binding on Dr. Fishbein, a letter some other person had.

Mr. Quaid:—It is a direct interrogatory, question by the defendant himself. The Court:—Let me see the answer. (Handed to Court.) Sustain the exception.

Q.—What did he say to you and what did you say to him? A.—He told me that he had taken my x-rays over to Dr. Turner's laboratory and that he and Dr. Turner went over them together, and while they showed I had some considerable trouble, that there were no cavities. He then went into a discourse on how unreliable x-ray pictures were. He compared them to having a photo taken, and he further explained that you could have several photos taken from the same pose, and that no two of them would look exactly alike, and that the same was true of x-rays. He said that the only sure way to determine the true condition of the lungs was with a stethoscope.

Q.—What did he say to you and what did you say to him? A.—I told Dr. Brunson that my month of treatments were up, and that rather than stay in El Paso another month in all the heat that I felt that I could take the treatment just as well in Chicago. He then went into a lengthy discourse on patients of his who left too soon, and without exception they all died within four to eight months after leaving. I told him that he must have misunderstood me; that I didn't intend to give up the treatment but to only take it in Chicago instead of El Paso. He then told me that that might work out all right but that there would be certain equipment necessary that would cost me not more than \$22.50. I told him I would be glad to get anything he suggested and follow any instructions to the letter. He said that before he could recommend that I do that he would like to give me a careful examination in the morning, and that if he found that I was well enough to leave, that he would arrange to get me the equipment, and that was all the conversation.

Q.—What did you say to him and what did he say to you? A.—He asked me into his private office, where he had me strip to the waist, and he went over my chest and back with the stethoscope. When he finished, he said "Young man, my advice to you is to stay here and take this treatment for another month. By that time you should be well enough to go back to Chicago. You will not be well enough to go right back to work, but I will get you the necessary equipment and give you enough medicine to last about three months, and at the end of that time there should not be anything that you would not be able to do. I do not want you to get discouraged, because you have improved remarkably since you have been taking the treatment; in fact, your improvement has been better than most of my patients."

I would say that your left lung was entirely well right now, and while I do not find any rales in the right lung, I am still a little afraid." I told him how disappointed I was, but that I was down in El Paso to get well, if possible, and that if his advice was to stay, that I would stay.

Q.—What did he say to you and what did you say to him? A.—I told him that my conversation with him of that morning had made me feel rather low down by his telling me that it would be necessary to be in El Paso another month. He said that maybe it would not be that long; that he would examine me again in about two weeks, and it was just possible that I might be able to leave then, due to the fact that I was improving so rapidly. He then started telling me about some insurance cases, when a man who was introduced to me as Dr. Young, came in, and I left.

Q.—What did he say to you and what did you say to him at that time? A.—I told the doctor again that I knew I could continue to show the same improvement that he maintained I was showing in El Paso, in Chicago, if I could continue to take his treatment back there. He answered this by stating that I really wanted to get completely well that I should follow his instructions; so I told him he was the doctor, and that I would follow his instructions implicitly.

Q.—When did you have the next conversation with Dr. Brunson? A.—In the afternoon of June 11, 1938.

Q.—At his office? A.—In his office.

Q.—What was said by him and what was said by you? A.—When the doctor was giving me the treatment he said "I understand that you know one of my cured patients." I told him that I didn't know the woman that he referred to, but that I had met her several times only to speak to. He then began a recitation of the condition both this woman (Mrs. Boise) and her husband were in when they came to him, and how he had cured Mrs. Boise in about three months, but that it had taken him about six months to cure her husband. He also told me that Mrs. Boise worked for him for several months after she was well.

Mr. Quaid:—We will continue with the cross interrogatories.

Fourth Cross Interrogatory:—State the sanatoriums, or hospitals, or clinics, where you were confined or treated for the disease from which you are suffering, giving the location of same, and the doctors operating same, and what the doctors told you constituted your physical ailments.

Mr. Harrell:—There is an objection to that, Your Honor. The question of treatment here by Dr. Brunson isn't in issue in this particular case, the only purpose in reading the parts of the deposition this morning is to connect up the delivery of this medicine.

The Court:—The Court knows that statement, that statement shows what sanatoriums there were, the sanatoriums will be admitted, but what the doctors told him about the case will not be.

Mr. Quaid:—That part of it is probably not admissible.

A.—My answer to cross interrogatory 3 covers this question.

Mr. Quaid:—That portion of cross interrogatory 3 that tells what sanatoriums he was in, I want to read that.

A.—In October 1936 the Mayo Clinic;

The Court:—Sustain the exception.

Mr. Quaid:—We except.

Fifth Cross Interrogatory:—Is it not a fact that both of your lungs, both anterior and posterior, contained rales, both upper and lower lobes? If you say they did not then state specifically what lung and what portions of the lung contained rales.

Mr. Harrell:—This is a lay witness; I don't think he is capable of testifying whether his lungs contained rales.

The Court:—Sustain the exception.

Sixth Cross Interrogatory:—State whether or not your case was diagnosed as chronic active tuberculosis.

Mr. Harrell:—We object to that, Your Honor, for the same reasons.

The Court:—The Court will sustain the exception.

Seventh Cross Interrogatory:—State when you contracted and first became aware of the condition of your lungs.

Mr. Harrell:—I am objecting to that for the same reasons.

The Court:—Sustain the exception.

Eighth Cross Interrogatory:—State if, on May 9, 1938, in addition to lung trouble, you did not experience pain in the stomach and also suffer from nervous indigestion.

The Court:—Now, gentlemen, if it is just a number of questions of that type you wish to except to their being offered in evidence and state the grounds of the exception, we can probably dispose of a lot all at one time.

Mr. Quaid:—I believe that is the last one.

The Court:—Sustain the exception.

Ninth Cross Interrogatory:—State if previous to May 9, 1938, you had visited El Paso and took treatment in any sanatorium in the city of El Paso. If so, give the date, name of the sanatorium, and for what you were treated, and the name of the doctor or doctors who attended you.

Mr. Harrell:—I am objecting to that; that still is not an issue here, treatments in any other sanatorium in El Paso.

The Court:—Sustain the exception.

Mr. Quaid:—Note an exception.

Tenth Cross Interrogatory:—State whether in that sanatorium and under those doctors x-ray pictures were made. If your answer is in the affirmative, state where those pictures are now and state whether or not those pictures were exhibited to Dr. Brunson by you.

Mr. Harrell:—Same objection, same reasons.

The Court:—Overrule the objection.

A.—Those pictures are in my possession and were exhibited to Dr. Brunson by me.

Twelfth Cross Interrogatory:—State whether or not, after returning to Chicago, you immediately felt bad and began to decline. If you answer in the affirmative, then state to whom you made such statement in El Paso.

Mr. Harrell:—We are objecting to that, Your Honor, for the same reasons.

The Court:—Let me see the answer. (Handed to Court.) The Court will sustain the exception.

Fifteenth Cross Interrogatory:—State whether or not, after returning to Chicago, you broke down again and decided to return to El Paso, and whether or not you decided to take the treatment that you had heard condemned while at the El Paso Sanatorium.

Mr. Harrell:—Objecting to that, Your Honor.

The Court:—The Court sustains the exception.

Sixteenth Cross Interrogatory:—State if, after returning to El Paso, you then commenced, on May 9, 1938, to take treatments from Dr. Brunson. A.—Yes.

Seventeenth Cross Interrogatory:—If, in answer to the foregoing, you say you did take treatments from Dr. Brunson, then state when you ceased to take the said treatments. A.—I ceased to take treatments from Dr. Asa Brunson on June 24, 1938.

Eighteenth Cross Interrogatory:—State whether or not, during the time you were taking treatment from Dr. Brunson, whether you indulged excessively in the use of liquor, and whether or not you indulged in smoking cigarettes. If you answer in the affirmative, then state how often and to what extent you so indulged, and whether or not Dr. Brunson advised you on several occasions that you would have to desist in the use of liquor and use of cigarettes. A.—I indulged in smoking cigarettes and did use liquor, but not excessively. At that time I was smoking approximately one package of cigarettes a day. My drinking was confined entirely to beer and would run from one to two glasses a day, up to and not exceeding six or seven in any twenty-four hours. Dr. Brunson did mention that he would like to see me cut down on cigarettes. He at no time mentioned drinking; in fact, on one occasion, in walking back to the hotel with him, he suggested that we stop in and have a glass of beer, which we did.

Nineteenth Cross Interrogatory:—State whether or not you know Mr. Hausman and state the name of the man of Hebrew descent who stayed at the Cortez Hotel, with whom you associated.

Mr. Harrell:—We object to any reference to a man by the name of Hausman. Any testimony regarding Mr. Hausman wouldn't be binding on Dr. Fishbein.

The Court:—The Court will overrule the objection. It is wholly immaterial.

A.—I know a Mr. Sam Hausman. Mr. S. A. Sandberg stayed at the Cortez Hotel at the time I did, and I associated with him while I was there.

Twentieth Cross Interrogatory:—State whether or not you know Bill Montgomery, whether or not you know Fred Knollenberg, whether or not you know Mrs. Mittie King, and whether or not you know Mr. Herbert Cox of Glendale, California, and whether or not you know Mr. Pundt.

Mr. Harrell:—I make the objection for the same reason.

The Court:—It will not be material at all unless the testimony, on further inquiry, seeks to impeach and offer the testimony of these witnesses. It is wholly immaterial. The Court will sustain it on the ground that it is immaterial unless it is connected up in some way and shows wherein it is material.

Mr. Quaid:—I thought Mr. Fred Knollenberg would testify. We put that in the main case; he treated Mr. O'Hara and he did improve.

The Court:—Sustain the objection.

Mr. Quaid:—I will offer the twenty-first, it is the same, and it is excluded.

The Court:—It is understood.

Twenty-Third Cross Interrogatory:—State whether or not you were x-rayed by Dr. George Turner on June 23, 1938. A.—Yes.

Twenty-Fourth Cross Interrogatory:—If, in answer to the foregoing interrogatory, you say you were, is it not a fact that at that time you were told that you were not well, and you were asked and urged to remain here and continue treatment at the clinic, but you stated that you were homesick for your family and wanted to go back to Chicago? State whether or not those are facts.

Mr. Harrell:—We object to that; unless something is proved here as to who told him, the question is ambiguous in that respect.

The Court:—Sustain the exception.

Twenty-Sixth-A Cross Interrogatory:—State whether or not you advised Dr. Brunson that it was imperative for business reasons that you should return to Chicago. A.—I did not.

Forty-Seventh Cross Interrogatory:—Is it not a fact that on June 9, 1938, one month after commencing the treatment of Dr. Brunson, you were greatly improved, that your digestion was normal, that you could eat well and satisfactorily, that the stomach pains had disappeared and that your heart was normal? If you state that they were not, give the name and address of the doctor or individual who examined you, stating that this was not a fact.

Mr. Harrell:—We object to that, Your Honor.

The Court:—Sustain the exception.

Forty-Ninth Cross Interrogatory:—Is it not a fact that on May 9, 1938, you weighed 150 pounds, that on June 23, 1938, immediately prior to leaving El Paso, you weighed 158 pounds?

Mr. Harrell:—Same objection, same reasons.

The Court:—Overrule the objection.

A.—On May 9 I weighed 152 pounds, and on June 23 I weighed 158 pounds.

Fifty-First Cross Interrogatory:—Is it not a fact that you obtained greater relief and made greater improvement under the treatment of Dr. Brunson than you did from any other doctor that ever treated you for this particular disease? A.—No.

DEPOSITION OF EDWARD M. BURKE, DIRECT EXAMINATION Taken in Chicago, May 23, 1939.

Mr. Edward M. Burke, Chicago, an attorney at law, a member of the firm of Loesch, Scofield, Loesch & Burke, told of employing Frank O'Hara to obtain the specimens and of the transfer of the specimens to the chemists.

The following cross interrogatories were offered by the plaintiff:

By Mr. Quaid:

First Cross Interrogatory:—State whether you are one of the defendant's attorneys in this cause. A.—Yes.

Seventh Cross Interrogatory:—When did you first employ O'Hara to act as a spy for you? A.—I will answer the first part of the question, which inquires as to when I employed O'Hara, and say that I employed him in the early part of May 1938. I did not hire him as a spy, but I hired him for the purpose of securing from a doctor, who was administering a secret remedy, a sample or portion of such secret remedy.

Mr. Quaid:—The last sentence is not responsive to the question and we do not care to read that.

Mr. Harrell:—I submit it was put in motion by the question.

Mr. Quaid:—It is an adverse witness.

The Court:—The Court sustains the exception.

Eighth Cross Interrogatory:—How much did you pay O'Hara for his services? State the total amount you paid O'Hara for his services in the Brunson case, including not only his salary but his expenses, and giving a detailed statement of his expenses. A.—From the time I employed Frank P. O'Hara, which I think was during the first week of May 1938, until June 30, 1938, I paid him the total sum of \$1,361, which included his salary of \$10 per day and expenses. I would say that about \$600 of that sum was salary and \$761 expenses, which expenses would include transportation from Chicago to El Paso and return and the money which he paid to Dr. Brunson for treatment during that period and the apparatus which Dr. Brunson sold to him to enable him to pursue his treatment at home in Chicago, Illinois.

Nineteenth Cross Interrogatory:—You have paid O'Hara for his services and for the depositions that he gave to you in New York. State whether or not you paid for and induced him to make false statements. *A.*—I did not pay him for making false statements and I did not induce him to make false statements. I paid for honest work and true statements and I think I got same.

Twenty-Second Cross Interrogatory:—Is it not a fact that in these cross interrogatories O'Hara admitted that he had gained approximately 8 pounds while in El Paso; that his hemorrhages had ceased; that his temperature had become normal; that he slept well; that he had improved?

Mr. Harrell:—I am going to object to that, Your Honor, the deposition of O'Hara would be the best evidence.

The Court:—Sustain the exception.

Twenty-Third Cross Interrogatory:—Is it not a fact that you had paid him to make the statements contained in the direct interrogatories? *A.*—It is not a fact. I paid him as and for compensation for the time consumed in going over the original letters which he had written to me and to refresh his recollection therefrom and for the time consumed in talking to him the day before the taking of the depositions on direct interrogatories, the time consumed in the submitting of said direct interrogatories to him, the time consumed on the day the written transcript of the direct interrogatories were submitted to him and the time consumed by him in going over said written transcript or the direct interrogatories and his answers thereto, the time consumed in considering the written cross interrogatories which you submitted at a later date and the time consumed by him in answering the written cross interrogatories submitted by you, and the consideration of said cross interrogatories and his answers thereto before the signing of same.

Twenty-Fourth Cross Interrogatory:—In addition to the payment for his per diem while in El Paso, and all of his expenses, state how much you paid O'Hara for answering the depositions you propounded to him? *A.*—I made no division of the amount of money I paid O'Hara as between depositions I propounded to him and the cross interrogatories which you sent later to be propounded to Mr. O'Hara. You sent no sum of money whatever for submitting your cross interrogatories to O'Hara nor for his consideration thereof, nor for his reading the same after they were written up. I paid O'Hara not only for the consideration of my direct interrogatories but also for his consideration of your cross interrogatories. That payment included the day that I went to see him at Rocky Crest Sanitarium near Olean, N. Y., when I submitted to him all of his letters to me and asked him to read and consider them and to refresh his recollection, so that he would be able to give his deposition on the following day. On the following day I again went to the sanatorium with the notary public and we spent about five hours on that day in submitting the direct interrogatories to Mr. O'Hara. After the direct interrogatories had been written up, they were taken to the sanatorium to Mr. O'Hara by a notary public and thereafter the deposition on direct interrogatories was signed by him. After Mr. O'Hara had signed the deposition on direct interrogatories, your cross interrogatories arrived and the notary public took your cross interrogatories to Mr. O'Hara and thereafter the notary public took Mr. O'Hara's answers to your cross interrogatories and transcribed the same on his typewriter and thereafter returned to the sanatorium and secured Mr. O'Hara's signature and oath thereto. The sanatorium is located in the mountains 5 miles from Olean, N. Y. For all of the foregoing services of Mr. O'Hara I paid him the total sum of \$100.

Twenty-Eighth Cross Interrogatory:—State where you got the money that you paid O'Hara. *A.*—I paid it from the funds of the law firm of Loesch, Scofield, Loesch & Burke.

Twenty-Ninth Cross Interrogatory:—Is it not a fact that this money was furnished by the A. M. A. to you or that you were refunded for the expenditures you made? *A.*—The money was not furnished by the American Medical Association prior to the time the services were rendered. The services were contracted for by me, in my discretion as the attorney for the defendant in this case and it was afterward billed by the firm of Loesch, Scofield, Loesch & Burke to the American Medical Association and said Association reimbursed the said firm for the expenditures so made.

Thirty-Second Cross Interrogatory:—State how many investigators you have had working on this case, including members of your firm, A. M. A. associates or hired detectives or investigators. Please give the names of these individuals. *A.*—Mr. J. H. McCoy is an investigator employed by the law firm of

Loesch, Scofield, Loesch & Burke. He has done some work on this case. Mr. F. P. O'Hara, who was employed by me personally and paid for his services as an investigator by the law firm of Loesch, Scofield, Loesch & Burke. J. H. McCoy and F. P. O'Hara are the only investigators who have worked on this case.

Thirty-Fourth Cross Interrogatory:—Attach said reports hereto and mark same for identification, showing who they contacted.

Mr. Harrell:—I am objecting to attaching such reports; they are clearly confidential, privileged in nature.

The Court:—The Court will sustain the exception. These reports are confidential.

Thirty-Seventh Cross Interrogatory:—State how much was paid those investigators and state what their expense account amounted to, and state fully the states and cities wherein they made investigations, and give the names of the individuals they contacted.

Mr. Harrell:—I object to that as immaterial to any issue in this case.

The Court:—The Court will sustain the exception, except as to Frank O'Hara.

Forty-Second Cross Interrogatory:—Is it not a fact that the said O'Hara either surreptitiously or otherwise secured letters or testimonials from Dr. Brunson or his wife and exhibited same to Mr. Brown, in this city, or had same copied and transmitted same to your office. Please attach all such instruments hereto and mark them for identification.

Mr. Harrell:—We object to that, Your Honor. I don't see how the witness could possibly know that.

The Court:—He is asking about some specific letters?

Mr. Harrell:—He is asking what Mr. O'Hara did here, that he obtained some letters surreptitiously.

The Court:—Let's see the question and answer. The Court sustains the exception.

Fiftieth Cross Interrogatory:—Mr. Burke, is it not a fact that the full power and influence and financial ability of the A. M. A. is back of Dr. Fishbein in this fight, and that you are being compensated from the funds of the A. M. A.?

Mr. Harrell:—Is there objection to that?

Mr. Quaid:—Yes.

Mr. Harrell:—I will waive the objection.

A.—Dr. Fishbein is the editor of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, and the American Medical Association is defraying his expenses in this lawsuit.

Sixty-Seventh Cross Interrogatory:—Also state what remuneration Crebs Beebe is receiving; also, John Doe and Richard Roe. *A.*—They have not testified and will receive no compensation.

Mr. Harrell:—If the Court please, I wish to read some of the cross interrogatories that counsel omitted to read.

Defendant thereupon introduced the following from the cross interrogatories of said witness:

Twenty-Fifth Cross Interrogatory:—Mr. Burke, as a reputable member of the bar, state whether or not you place any confidence in the truth and veracity of a paid hireling who is seeking, in a questionable manner, to obtain information favorable to your case or any other case. *A.*—I placed confidence in the truth and veracity of Frank P. O'Hara. He was paid by me for honest services rendered. He was not and is not a hireling in any sense of the word. He sought in the only way possible to obtain from Dr. Asa Brunson a sample or portion of the liquid which he claims is a treatment for tuberculosis. Dr. Brunson refuses to disclose what his said treatment contains.

Mr. Quaid:—Just a moment, Your Honor. I want to object to that portion on the bottom of page 32. I want to object to that on the ground that it is not responsive to the answer—I mean to the question, in the first place, and in the second place it is a matter that is not within the knowledge of Mr. Burke.

Mr. Harrell:—I submit that is the continuation of the answer.

Mr. Quaid:—That portion of the answer is not responsive.

Mr. Harrell:—You raise the question of confidence in the truth of a paid hireling, and he is testifying what he did.

The Court:—The Court will sustain the exception.

Eighteenth Cross Interrogatory:—State who suggested O'Hara to you as a good stool pigeon to send to El Paso to seek to insinuate himself into the good graces of Dr. Brunson. *A.*—No one suggested Mr. O'Hara to me as a good stool pigeon, nor as a stool pigeon, nor as a pigeon, but the occupation of O'Hara and the position which he held in his lifetime suggested to me

that he would be a high class, honest man. I did not send O'Hara to El Paso to insinuate himself into the good graces of Dr. Brunson—

Mr. Quaid:—We object to that part. That part is responsive, and the rest of the answer is not responsive. He has answered it, he said he did not send him except because he thought he would do him a good job. That is all right.

The Court:—The Court will sustain the exception to that portion of the answer.

Twenty-Sixth Cross Interrogatory:—Is it your practice to hire questionable individuals and pay them to testify for you in your cases? A.—Heretofore I have never found it necessary to hire an individual, questionable or otherwise, to determine from a physician and surgeon the ingredients or the contents of a remedy which he was administering. This is the first time that I have ever found it necessary to do so. The physicians and surgeons that I have encountered have always been ready and willing to state the contents of any treatment which they were administering to human beings. I do not consider Frank P. O'Hara a questionable individual. I did not pay him to testify in the case. I paid him for the investigation which he conducted for me and I paid him a reasonable sum for his time in conducting the investigation for me and a reasonable sum for his time consumed in submitting to questions and in making answers in his deposition on direct and in submitting your questions and in making his answers on your cross interrogatories in said deposition.

Sixtieth Cross Interrogatory:—State why they were delivered to you, the man who had paid presumably to secure them in an unfair and unethical manner, and also the man who is defending this case and seeking to show the contents thereof as being dangerous or detrimental. A.—I do not consider that they were secured in an unfair or unethical manner. I know of no other method or manner of securing from a physician and surgeon a secret remedy for tuberculosis or any other disease. As to the reason why they were secured in the manner indicated, I say to you that it was because I wanted to secure an analysis thereof and determine the contents and the ingredients of this secret alleged remedy. The said remedy is secret because to date Dr. Asa Brunson has refused to reveal even to the Court in this case the contents or ingredients of said secret remedy.

TESTIMONY OF DR. LLOYD ERVIN HARRIS
ON DIRECT EXAMINATION

Questions by Mr. Harrell:

Dr. Lloyd Ervin Harris stated that he lives in Norman, Okla., and was born near Ryan, Indian Territory, in September 1900. He is professor of chemistry in the University of Oklahoma. He went to the University of Oklahoma, where he received four degrees, the degrees of pharmaceutical graduate in 1920 and the degree of pharmaceutical chemistry and bachelor of science of pharmacy in 1922. He then did graduate work, receiving a master of science degree in chemistry with botany minor in 1924. In February 1925 he went to the University of Wisconsin and in August 1926 received a doctor of philosophy degree. He wrote a thesis for his master's degree at the University of Oklahoma in 1924. The subject of that thesis was the analysis of a number of remedies that were used in the treatment of dog distemper. In 1926 he was the author of a thesis on phytochemistry, which means chemistry of Bixa orellana. A part of that was published in the form of a monograph by the University of Wisconsin. He is a member of the Sigma Xi which is a graduate scientific society; member of the American Pharmaceutical Association; member of the Oklahoma State Pharmaceutical Association, and other organizations of similar character, also a member of the Committee of Revision of the United States Pharmacopeia.

Q.—Doctor, in your work have you ever analyzed medicines? A.—I am frequently called on to analyze medicines of various kinds.

Q.—Doctor, now I am calling your attention to May 13, 1939. Did you meet a gentleman by the name of Mr. E. M. Burke in Chicago? A.—I met a gentleman who told me his name was E. M. Burke, and I have every reason to believe it was he. [Dr. Harris then told how he received the specimens of the Brunson material.]

Q.—What did you do with the medicines after you returned to Norman, Oklahoma? A.—At the first opportunity I took the medicines and in a characteristic pharmaceutical fashion I looked at them again. Then I opened them, opened one of them and smelled it, observing what I could from the sense of smell. The next thing I did was to take a clean stirring rod and take a drop of it and put it on the tip of my tongue and observed the taste and effect on the tip of the

tongue and toward the back of the tongue as it worked in that direction. Then I made certain physical measurements. I determined the weight of it as compared to water at room temperature. I then determined its index of refraction, then continued with a little more detailed analysis. From the sense of smell and the sense of taste I could detect that there was something in it, in the medicine that would be volatile.

Q.—Would be what? A.—Volatile.

Q.—What does that mean? A.—Volatile means that it goes up into the air in the form of a gas. The solubility of medicines frequently gives you a very important clue. I found that this medicine was practically insoluble or insoluble in water.

Q.—What do you mean by insoluble? A.—Insoluble means that it will not mix with it to form a clear solution. I then decided that steam distillation—

Q.—What do you mean by that? A.—By taking a flask and putting water into it, under which a fire may be placed and causing the water to be changed into steam. This steam then was conducted through a small portion of the medicine, causing these volatile ingredients to which I referred a moment ago to go over into the volatile condition. They were then recondensed into liquid form by means of a condenser which was water jacketed to cool it. This was done in a series of steps. The first fraction I collected about 6 or 8 cc., about two tablespoonfuls of water on which floated some oily-like material having a very characteristic odor. The second fraction I collected 1 fluidounce of water on which floated a small quantity of insoluble material that was oily in character and had a slightly different odor. The third fraction, which was also collected in the amount of 1 fluidounce of water, was practically odorless. There was some slight trace of odor, but that was all. That left then in the flask the non-volatile portion, which, on examination by the sense of smell and sense of taste, was shown to have been deprived of those ingredients that had taste and smell.

Q.—Now, does that in a general way complete your analyses, Doctor? A.—No, sir. From there I had to make some specific chemical tests. In order that I might determine a little bit more thoroughly the nature of the material with which I was working I put some of it in a small distilling flask and heated it directly. This started to boil at a temperature of, in centigrade, about 170, the temperature, the thermometer, continued to rise; after a few drops of the material had come over the thermometer went up rather hurriedly to a temperature of approximately 330 degrees centigrade. For the information of those who are not familiar with degrees centigrade may I offer this information: That the boiling point of water is 100 degrees centigrade as compared to approximately 212 degrees Fahrenheit. So to get degrees centigrade to Fahrenheit you have to make a definite correction. That correction is multiplying by 1.8 then adding 32 to your result. After I had done this I determined the index of refraction of the portion that was nonvolatile from the steam distillation. I also determined its solubility or insolubility in various solvents and carried out certain chemical tests to find out the nature of the material, likewise the ingredients that were floating on the portion that had been brought over by the steam; I made certain chemical tests on that.

Q.—When did you complete your analysis? A.—The analysis was completed on Wednesday a week ago; a week ago last Wednesday.

Q.—Was the liquid or medicine that you were analyzing the same medicine that you received from Mr. Burke on May 13 of this year? A.—Yes, sir.

Q.—What did your analysis disclose? A.—The analysis showed that it was about 95 per cent light liquid petrolatum, commonly known as light mineral oil, sometimes known as light liquid albolene; about 5 per cent—that is approximately now—of the ingredients that were volatile.

Q.—Of what, Doctor? A.—About 5 per cent of the ingredients that were volatile that had come over in steam distillation. This showed principally to be cineol, which is also known as eucalyptol. That was very definitely shown to be in the first fraction by sense of smell, taste and chemical test. In the second fraction there was very definitely a peppermint-like odor. This was shown to be menthol. There was a trace of turpentine or terpene-like odor, which I did not identify. However, oil of eucalyptus on aging develops this odor, so I am not in a position to say whether this was added in another form or in the form of oil of eucalyptus.

Q.—Now, Doctor, to sum up in just a few words, what did this medicine contain, give us the percentages of same? A.—

Mineral oil approximately 95 per cent, oil of eucalyptus—in my best judgment it was oil of eucalyptus—about $3\frac{1}{2}$ per cent—that could vary just a little bit either way, and a small quantity of menthol, not to exceed 1 per cent, and possible traces of other ingredients.

ON CROSS EXAMINATION

Questions by Judge Sweeney:

Q.—Doctor, when did you arrive in El Paso? A.—Monday morning, this last Monday morning.

Q.—You have been here ever since then? A.—Yes, sir.

Q.—Have you discussed this case with any one, or the testimony that you were to give in this case? A.—I discussed it with the attorneys, yes, sir.

Q.—With any one else? A.—I talked in a general way with other people.

[The cross examination brought out that Dr. Harris knew in a general way what had been found by Drs. Schoeffel and Muehlberger.]

Q.—You are to be reimbursed for whatever expense you have been put to? A.—Yes, sir.

Q.—And you are to be paid for your analysis? A.—I expect to be.

Q.—You expect to be? Are you connected in any way with the A. M. A., Doctor? A.—I am not.

DEPOSITION OF EMMETT I. DENTON

Taken in El Paso County, Texas, on May 31, 1939.

Mr. Emmett I. Denton testified that he had been acquainted with Dr. Asa Brunson since 1929.

Q.—Did he ever give you any medicine or remedy? A.—He never did give it to me himself.

Q.—Who gave it to you? A.—His girl in the office, the office girl.

Q.—Do you know how she happened to give it to you? A.—He had a large oxygen tank with a hose about this long and an atomizer and put it in my mouth and gave me ten or twelve sprays and told me to breathe it deep.

Q.—Did he ever give you a bottle of his medicine? A.—Yes, sir.

Q.—What did Dr. Brunson give you? A.—I don't know what it was.

Q.—It was a bottle of medicine? A.—A bottle of medicine, no label on it.

Q.—About what size bottle of medicine? A.—Oh, I think it was about as big as that there (referring to bottle), about a 3 ounce bottle.

Q.—Now, just state what, if anything, Dr. Brunson gave you. A.—Well, I couldn't say what it was, it was just a treatment for tuberculosis.

Q.—Was it a liquid in a bottle? A.—Yes, sir.

Q.—What did you do with that? A.—I took it home and used it for a spray down my throat twice a day.

Q.—Did you ever give it to any one? A.—Yes, sir.

Q.—If so, to whom did you give it? A.—I gave it to a girl called Sadie Hayes.

Q.—I will ask you whether or not you gave Sadie Hayes the same medicine or liquid that Dr. Brunson gave you? A.—Yes, sir.

CROSS EXAMINATION

By Mr. Quaid:

Q.—How much did you have left when you gave Sadie Hayes that medicine? A.—Well, I had almost—I don't know if it was a bottle that size (referring to bottle), it was a full bottle, and an atomizer I had was full also.

TESTIMONY OF SADIE HAYES ON DIRECT EXAMINATION

Sadie Hayes, Hotel Vogel, El Paso, came for her health and has been working for the WPA for about three months. She is acquainted with Mr. J. H. McCoy and with Dr. Felix Miller.

Q.—Do you remember a gentleman by the name of Emmett I. Denton? A.—Yes.

Q.—Did you ever at any time last year receive any article from this man Denton, Emmett I. Denton? A.—Yes, I received a bottle of a liquid which he received from Dr. Brunson for treatment.

Q.—Did he tell you from whom he received it? A.—Yes.

Q.—What did you do with that bottle? A.—I gave it to Dr. Felix Miller.

ON CROSS EXAMINATION

Questions by Mr. Quaid:

Q.—Miss Hayes, how long had you known Mr. Denton? A.—Oh, for possibly two years.

Q.—Who approached you and asked you to get this medicine from Mr. Denton? A.—Well, I had heard about Mr. Denton, the treatment, the results of the treatment, and I had talked about it to Dr. Miller, and then one day he asked me if I had any of this medicine or if this man had any, and this man volunteered to give it to me.

TESTIMONY OF J. H. MCCOY ON DIRECT EXAMINATION

Questions by Mr. Brown:

James H. McCoy, Chicago, Illinois, testified that he was acquainted with Emmett I. Denton and Sadie Hayes.

Q.—Where did you first meet Mr. Denton? A.—I met him in the Sellers Sanatorium last August, some time last year.

Q.—Where did you first meet the witness who just left the stand, Sadie Hayes? A.—Dr. Miller's office.

Q.—When was that? A.—That was around August 15 or 16 of last year, 1938.

Q.—What occurred at that meeting in Dr. Miller's office? A.—Dr. Miller called me at the hotel and told me he had gotten medicine of Dr. Brunson's, if I would come up there, and I went up there and he was there and showed me a bottle and told me he was going to seal it and tape it up and everything and put his initials on it, and the date, which he did, and he handed it over to me either August 15 or 16.

Q.—Who was present on that occasion? A.—Miss Hayes, Dr. Miller and myself.

Q.—What did you do with the bottle? A.—I took that bottle with me to Chicago and I put it in the vault up there in our office under lock and key in the drawer I have up there, until May 17 when I took it over to Dr. Muehlberger at the Cook County Hospital, and I turned it over to him.

Q.—Did you turn over to Dr. Muehlberger the same bottle and the same contents you had received from Dr. Miller in the presence of Sadie Hayes? A.—Yes, sir.

ON CROSS EXAMINATION

Questions by Judge Sweeney:

Q.—You have been pretty much over the United States in the investigation of this case, have you not? A.—I have—not on this case, no.

Q.—Where have you been in reference to this case? A.—This case? Missouri, Arkansas and Texas. I guess I was up to New Mexico too, Albuquerque.

Q.—Louisiana? A.—No, I didn't get time to go down there. Oh, yes, I was, I was at the town of Cotton Valley, Louisiana, last year.

Q.—Cotton Valley? A.—Yes, that is right, something like that.

Q.—In your trips through Missouri, Arkansas, Texas, New Mexico and Louisiana you met quite a number of Dr. Brunson's former patients, did you not? A.—Yes, sir.

Mr. Brown:—We object to those matters we have not gone into, we have not gone into those matters, and if they want to make him their witness in chief they may do so later on.

The Court:—The Court sustains the objection.

Judge Sweeney:—I have not asked anything, it was in anticipation, I just want to ask him the question had he met them.

The Court:—Whether he saw them or did not meet them would be immaterial.

Q.—Now, Mr. McCoy, have you got the letters that Mr. Burke was asked to attach as exhibits to his deposition which he stated—you were in the court room and you heard the depositions?

Mr. Brown:—Your Honor please, we object to that, it is immaterial and irrelevant.

The Court:—As to whether he has them or not, I will let him answer that question. If you are seeking to introduce them that would be material. That question was inquired about this morning, and it was stated he would be put on the stand. I will permit him to answer this question.

Q.—Do you have the letters with you? A.—Not with me, no, sir.

Q.—And you were not asked to bring them to El Paso? A.—No, sir.

SATURDAY, JULY 15, 1939

GAS GANGRENE IN CIVIL LIFE

The death rate from gas gangrene is still appallingly high. The mortality rate of gas gangrene in civil life has been estimated by Millar¹ and by Eliason² and his co-workers. Millar collected 607 cases occurring in civil life from the beginning of the "post-Lister" period to 1930. The mortality rate in this series was 49.7 per cent, while the mortality from the same infection of the American Expeditionary Forces in France was 48.52 per cent. Eliason and his co-workers collected 349 cases reported from 1930 to 1936. In a group of cases in which gas gangrene developed after amputation for arteriosclerotic or diabetic gangrene the mortality was particularly high, 59 per cent for the entire group and 75 per cent for the diabetic. In a group of cases following surgical procedures other than amputations, the mortality was 41 per cent when serum was used and 76 per cent for cases in which serum was not used. The mortality in 109 cases reported by Callander³ and his co-workers was 51 per cent. Because the prognosis of this dreaded infection depends largely, if not entirely, on early recognition and prompt treatment, the lessons learned during the World War need to be emphasized as well as the advances of the postwar period. Two notions appear to be largely responsible for the lack of awareness of gas gangrene by physicians: gas gangrene is rare in peace time and it always presents itself in its typical grave form.

Recent pathologic studies have established that gas gangrene is caused almost exclusively by anaerobic bacilli. As a rule, a number of anaerobes are found associated in symbiosis with aerobic organisms such as streptococci or the staphylococci. No one anaerobe can be said to be responsible for the infection. The toxins produced by aerobic organisms create within the tissues conditions favorable to the growth and pathogenic action of the anaerobes. The clostridia cultured

from cases of gas gangrene in order of their frequency are *Clostridium welchii* (*Bacillus aerogenes capsulatus*; *B. perfringens*) in from 80 to 100 per cent of the cases, *Clostridium oedematis maligni* (*vibrio septique* of Pasteur), *Clostridium novyi* (*oedematiens*), *Clostridium sordelli* and *Clostridium histolyticum*. The anaerobes inhabit the soil and the alimentary tract of man and animals, dairy products and clothing. Research indicates that *Clostridium welchii* is ubiquitous. However, most of these strains are not pathogenic. These organisms give rise to exotoxins which act as aggressins. In the presence of such exotoxins the clostridia take on a virulent pathogenic character and rapidly lead to gangrene and death. Deeply lacerated, contused soiled wounds, compound fractures, hematoma and interference with the blood supply create favorable conditions for the growth of anaerobes. Callander lists, as varieties of trauma which predispose to gas gangrene, crushing and lacerating accidents, particularly compound fractures, where street and farm dirt rich in anaerobes gains access to injured tissues, particularly muscles; gunshot wounds and other punctured wounds into which anaerobes are introduced by contaminated missiles, mud, gravel and bits of cloth, and injuries to the gluteal and peroneal regions where fecal contamination readily occurs. Furthermore, abortions and instrumental delivery occasionally have caused gas gangrene of the uterus, hypodermic or intramuscular injections have occasionally been followed by gas gangrene, and gas gangrene may follow clean surgery, particularly amputations for arteriosclerotic or diabetic gangrene.

The symptoms include pain at the site of the wound, mounting fever and acceleration of the pulse, followed by constitutional symptoms of grave intoxication such as stupor, coma and delirium. The local signs are those of a rapidly increasing swelling, a serous or sero-sanguineous discharge, a mottled discoloration of the skin, crepitation of the tissues, escape of gas bubbles when the edges of the wound are spread and the characteristic odor. Early x-ray examination is capable of demonstrating gas in the depth of the tissues long before it can be elicited by palpitation or percussion.

Prophylaxis implies a certain amount of awareness and early recourse to x-ray examination and to smears and cultures from the depth of the wound in suspected cases. The question of what lesions to treat by the method of débridement and the administration of anti-serums must be left to the experience and the judgment of the surgeon. The use of serum both as prophylactic and as curative therapy, while still in an experimental state, is definitely indicated. Thus the statistics of Eliason and his co-workers show a mortality rate of 25 per cent in cases treated with serum as compared with 49 per cent in cases not so treated. Bates⁴ showed a reduction from 50 per cent to 18 per cent with the use

1. Millar, W. M.: Gas Gangrene in Civil Life, *Surg., Gynec. & Obst.* **44**: 232 (Feb.) 1932.

2. Eliason, E. L.; Erb, W. H., and Gilbert, P. D.: *Clostridium Welchii* and Associated Organisms, *Surg., Gynec. & Obst.* **64**: 1005 (June) 1937.

3. Callander, C. L.; Haim, Arthur, and Maximov, Alexis: Gas Gangrene: An Analysis of 109 Cases Encountered in Civil Practice, *Am. J. Surg.* **42**: 811 (Dec.) 1938.

4. Bates, M. T.: Gas Gangrene: A Review of Thirty-Two Cases With Special Reference to the Use of Serum, Both Prophylactic and Therapeutic, *Ann. Surg.* **105**: 257 (Feb.) 1937.

of serum. Kelly⁵ and his co-workers are enthusiastic over the results of roentgen treatment of gas gangrene. They report 143 cases treated by them and others since 1928 with results which far surpass those obtained with serums, débridement and amputations. They are inclined to regard roentgen therapy in gas gangrene as a specific and state that, if it is employed during the first twenty-four hours, recovery will occur in all cases. The discussion would not be complete without mention of sulfanilamide. However, judgment as to the efficacy of sulfanilamide and of roentgen therapy must be suspended until further experience.

NON-PERUVIAN VERRUGA

Carrión's disease is also known under the names of verruga peruana (chronic stage) and Oroya fever (acute stage). The identity of the two conditions (verruca and fever) was dramatically demonstrated by Carrión in 1885 and confirmed afterward by various workers, among them Noguchi, and by Rebagliati and Gastiaturu. Barton found the causative agent in 1909, which Strong and the Harvard commission named *Bartonella bacilliformis* in his honor in 1913. Battistini and Noguchi later grew this organism in cultures.

Because of a number of peculiarities, the two stages (verruca and fever) have long attracted international attention; American scientists have been prominently identified with researches into their etiology and transmission. Only a few months ago a Harvard University commission returned from a field study of the disease in Peru. One point usually emphasized is the geographic limitation of the condition; until recently it was definitely identified only in the rather sharply defined Andean area (narrow valleys on the western slopes, latitude from 8 to 13 south, altitude from 1,000 to 12,000 feet) from which it gets its name—Oroya, Peru. It has never been contracted in the lower coast region or reported from the eastern side of the Andes. Occasionally, as may be seen from textbooks on tropical diseases, there have been unverified reports as to the presence of verruga peruana in similar areas of neighboring countries, as Bolivia, Chile and Ecuador. Some have identified as verruga the disease attacking Pizarro's soldiers in 1531 at Coaque, Ecuador, although this was later discredited. Mendoza reported in 1905 its prevalence in the Amazon basin in Bolivia, and Trigo Arce in 1935 reported cases clinically of verruga peruana in the Yungas region of Bolivia, where the natives called it "septique" and "siete." However, the first complete account of a disease clinically and bacteriologically resembling verruga peruana outside of Peru seems to be the one just published by the director of the Lleras-Acosta Infectious Disease Institute in Bogotá.¹ The epidemic seems to have attracted notice first in 1936,

when it was found in the basin of the Guaitara River, a fertile, mountainous area in southern Colombia, having invaded an area of 1,000 square kilometers inhabited by 100,000 persons and including thirteen towns. Whole families were attacked. Both mild and severe cases were observed. The disease ran a fatal course of from four to eighty-seven days in some instances; in others convalescence began as late as the sixtieth or seventieth day. The mortality reached 40 per cent, and it is estimated that 1,800 persons died from the disease from January to September 1938.

The present condition is characterized by a generalized stage with low fever, pain, rapid pulse, anemia and difficult breathing, followed from thirty to sixty days later by a granulomatous eruption with almost complete absence of general symptoms. The characteristic anemia is invariably present. The parasite, found in the red corpuscles of fever patients, and in verrugas, is a multiform, coccobacillary *Bartonella*, which, when inoculated, kills guinea pigs and may be grown in cultures. It was transmitted to guinea pigs by lice from a human patient. Sand fleas (*Phlebotomus*) have not been discovered in the area, after careful search. *Pinglio*, a plant of the *Euphorbia* family, is prevalent, and the guinea pig is almost invariably a domestic animal in the houses of the Indians. Lice, fleas and chiggers are common parasites of the inhabitants.

The high death rate and epidemic character of this latest outbreak recall the situation in Peru, where 7,000 deaths were reported among workers building the Oroya railroad in 1870. The Colombian government has recently taken active measures to combat the epidemic, organizing under the health authorities of the region a special brigade, opening seven emergency hospitals, and appropriating 60,000 pesos (\$35,000) for medical aid. Plans also include the permanent improvement of dwellings. The new Colombian focus justifies a surmise that similar situations may exist somewhere else in tropical areas thus far unexplored or little known.

THE CONSUMER TREND

The principle of *caveat emptor* daily loses standing. A meeting of consumers and business representatives was called at Buffalo June 5 and 6 by the National Association of Better Business Bureaus. These bureaus have done much in recent years to protect the consumer against fraud and misleading advertising, although their principal aim is to maintain the confidence of the consumer in business and in advertising. Such organizations indicate that business finds it desirable to protect the consumer for its own protection.

The consumer movement is of special interest now because of the recent legislation which has been passed for the protection of the consumer—the Food, Drug and Cosmetic Act and the Wheeler-Lea amendment to the Federal Trade Commission Act. Other government agencies which aid the consumer include the Bureau of

1. Patiño-Camargo, L.: *Bol. Of. San Pan.*, April 1939, p. 305.

Home Economics, the Post Office Department and the Bureau of Standards. For many years the A. M. A. Bureau of Investigation has cooperated with the Better Business Bureaus. Information is disseminated directly to consumers by various bureaus conducted as an integral part of the American Medical Association. In addition to the Bureau of Investigation, these include the Councils on Medical Education and Hospitals, on Pharmacy and Chemistry, on Physical Therapy and on Foods, the Bureau of Health Education, the Bureau of Exhibits and the Library.

The Buffalo meeting included manufacturers, distributors, retailers, advertisers, representatives of government agencies, consumer study groups and individual consumers. There was little evidence of a general desire to replace present systems of business with cooperatives. Indeed, it was acknowledged that the radical in the consumer movement was as much of a danger to the consumer as to business. The group appeared to be in sympathy with established methods in American business. A desire was expressed to continue activities on the only basis which was generally satisfactory—cooperation and an honest attempt on the part of each party to study and understand the problems of the other. Certain business representatives decried the fact that certain consumer groups had criticized business and advertising on the basis of a few black sheep. The consumer group did not retaliate, however, by accusing certain manufacturing interests of judging the consumer movement on the basis of the activities of the most radical elements.

From a theoretical standpoint, one speaker urged, it would be more important for the consumer to be able to determine his relative need for various articles than to determine which particular brand of an item or which particular grade of an item would give him the most for his money. However, the practical problem today is for the buyer to obtain his money's worth in purchasing what he wants, whether he has been properly educated as to his relative need for that item or not.

Certain advertising representatives were the only ones in the conference who even intimated that they were not entirely in sympathy with the consumer movement. One such representative went so far as to intimate that it was undesirable to educate the consumer as to his necessities, since it was the privilege of an American to spend his money foolishly in the purchase of luxuries. The particular medium of advertising which he represented has, incidentally, formulated a program of reform which he presented as arising from its own initiative but which appeared to be principally attempts to avoid conflict with the Federal Trade Commission under the new stipulations granted it by the Wheeler-Lea amendment.

A primary problem in consumer education and, incidentally, one not fully stressed in the business-consumer conference, is the means of fixing in the minds of consumers the sources from which they may

obtain authentic information. It is far more important that they remember these sources than it is for them to recall the methods of determining whether a given product is standard or substandard and whether one brand is a better buy than another.

Consumer education is not a new concept. The fact that an organization which was created by business itself finds it expedient to call a conference of consumers and its own representatives and to discuss the problems openly leaves no doubt that the movement has developed into an important cog in the machinery of American business.

Current Comment

A NONSPECIFIC FACTOR IN RESISTANCE

The relation of physical fitness to the ability to withstand infection has proved highly variable in practice, although the belief that the physical condition affects susceptibility to infection in some instances has been amply substantiated. Experimental evidence seems to indicate that several factors may be involved.¹ An especially interesting contribution to this subject has been reported recently by Locke.² For the rabbit, the experimental animal used in his experiments, fitness was approximated in terms of warming time, that is the number of minutes required for the recovery of 3 degrees of body temperature following chilling to a point between 95 and 96 F. Various factors producing circulatory impairment, including shock, the administration of morphine, exposure to overheating, deprivation of food and fatigue, were studied in relation to their effect on warming time. When animals affected by these procedures were compared with normal animals in their resistance to survive the intravenous injection of virulent type I pneumococci, it was found that the warming time reveals low-grade resistance in the rabbit with quantitative precision. Locke concludes therefore that fitness as measured in this manner is a factor of resistance in the rabbit to the extent that it reflects adequacy of capacity for sustaining circulation. Adequate circulation is essential for the efficient functioning of the mechanisms maintaining tone and body temperature. Impairment in circulatory capacity sufficiently severe to produce decrease in capacity for resistance can be detected in the rabbit through the associated impairment in the capacity to maintain tone and body temperature. Both spontaneous and artificially induced improvement in capacity to sustain circulation are accompanied by correlated improvement in ability to survive intravenous injection with small numbers of virulent type I pneumococci. These interesting observations suggest that at least one of the factors in the increased resistance of physically well persons to infection lies in the capacity to maintain improved circulation. As an element of purely relative nature, however, it may also explain the extreme variation in such resistance as observed in practice.

ORGANIZATION SECTION

GRADUATE MEDICAL EDUCATION

A PROGRESS REPORT OF THE FIELD STUDY ON GRADUATE MEDICAL EDUCATION IN THE UNITED STATES
BEING CONDUCTED BY THE COUNCIL ON MEDICAL EDUCATION AND HOSPITALS

DISTRICT OF COLUMBIA

The annual scientific assemblies of the Medical Society of the District of Columbia are devoted to continuing the education of practicing physicians. The three day assembly consists of lectures, medical and surgical clinics, demonstrations and exhibits. In May 1939 the assembly was devoted to a complete review of gastro-enterology. Approximately half of the speakers were out of district physicians. Meetings were held in a local hotel. Nonmembers of the society were charged a registration fee of \$3. Income from technical exhibits and appropriations from the District Medical Society aid in financing the graduate program. Registration has increased from 501 in 1936 to about 600 in 1939.

The George Washington University School of Medicine has offered one or two day clinics for graduates each February since 1933. Lectures, clinics, symposiums and demonstrations are given on various subjects by instructors at the medical school. Alumni of the university are invited. No registration fees are charged. The number of physicians attending approximates 250.

Georgetown University School of Medicine has provided a three to six day general review for graduates at the medical school and affiliated hospitals each September since 1936. In 1939 the three day course was held in June. Lectures, clinics and symposiums are given generally by the medical school instructors. About 180 physicians, alumni and friends of the university, attend each year. No registration fee is charged.

Beginning in 1937 Howard University College of Medicine, in cooperation with the United States Public Health Service, the Health Department of the District of Columbia and the Freedmen's Hospital offered a three months postgraduate course in venereal disease. Applicants, usually on recommendation of state health officers, must be graduates of approved medical schools within ten years of application and must have completed one year of internship in an approved hospital. Registration is limited to ten physicians for each of three sessions a year. A stipend of \$100 a month is paid to those who come from sections 25 or more miles away from the District of Columbia. Twenty-five registered in 1937-1938 and seventeen in 1938-1939.

The weekly schedule includes four hours' experience in the urologic clinic, taking histories and examining and treating patients under supervision. Six hours is spent in the clinic in syphilology, where similar experience is afforded, including dark field examinations. Three hours a week is devoted to social service assignments. Lectures, in which epidemiology is stressed, clinical pathologic and round table conferences and periods for assigned reading complete the schedule. Dr. H. H. Hazen is director of the postgraduate course.

The Army Medical Library has made available to physicians, through an interlibrary loan service, the most extensive collection of medical literature. Publications may be borrowed by application through responsible libraries. In the Index Catalogue of the Surgeon General's Library is listed the present accumulation of medical reference material.

Because of the increasing number of periodicals, monographs and textbooks on medicine in current use, it has been difficult for the practicing physician to have at his disposal all the literature that he may require. To meet this need a nonprofit organization was formed in 1934 by cooperative agreement between the Army Medical Library and the libraries of the United States Department of Agriculture, the Geological Survey and the Bureau of Standards. This organization, known as the Bibliofilm Service of Washington, D. C., has perfected

microfilms which are photographs of the printed page in bound or unbound volumes. Microfilms are developed on 35 mm. moving picture film at a price of 1 cent a page plus a 20 cents service charge for each article copied. They can be read by means of a small hand lens or with the aid of a desk projector which is available commercially. Science Service, the Chemical Foundation and the United States Navy and others cooperated in the development of this projector. It is now possible to acquire a library at low cost and to file microfilms in a remarkably small space.

The medical services of the Army, Navy, Veterans Administration and United States Public Health Service all provide postgraduate training for their own personnel.

There are 2,141 physicians licensed to practice in the District of Columbia, of whom 872 are members of the Medical Society of the District of Columbia.

NORTH DAKOTA

In 1935 the North Dakota State Medical Association appointed a committee on maternal and child welfare with Dr. J. H. Moore, Grand Forks, as chairman and the state health officer as secretary. The major objective of this standing committee, which now consists of ten members, has been to continue professional education in obstetrics. Local committees were formed to enable the physicians in each of the thirteen district medical societies to formulate their own programs. The North Dakota State Department of Health has financed the instruction with federal funds.

An out of state speaker spent two weeks in North Dakota in September 1936. Two day meetings were held in each of five cities. The district committee on maternal welfare was in charge of arrangements and during the first night of the seminar a stated meeting of the district medical society was held. Five subjects in obstetrics were discussed by the visiting physician. Local physicians also participated by presenting symposiums in which three members of the state association's committee discussed infections, toxemias and hemorrhages. Whenever possible case histories were discussed and hospital facilities were utilized. Seminars were attended by from twenty-five to thirty-five physicians in each district.

In 1937 it was recommended that pediatricians be included on the state association committee and that instruction in pediatrics and health education be added to its activities. During 1937-1938 medical extension training was continued in five other cities of the state, and an out of state obstetrician and pediatrician conducted courses similar to those given in 1936. In response to inquiry, practicing physicians stated that they favored the state association's postgraduate program and found the month of October most convenient for these courses.

The second phase of the committee's activities in North Dakota was initiated in May 1939, when the state health officer made available funds so that practicing physicians might attend a five days course in obstetrics at the University of Minnesota's Center for Continuation Study in Minneapolis. Of forty-eight who applied, ten rural physicians were selected on vote of members from as many district societies. Tuition, travel expenses and maintenance were provided.

It was proposed to offer a series of seminars in obstetrics and pediatrics in nineteen places over the state during the coming year.

Of the 508 physicians licensed in the state of North Dakota, 387 are members of the state medical association.

MEDICAL LEGISLATION

MEDICAL BILLS IN CONGRESS

Changes in Status.—H. R. 6635 has been reported to the Senate, with amendments, proposing to amend the Social Security Act in numerous respects. The reported bill does not contain Senator Wagner's amendments proposing to authorize the Social Security Board to make provision for furnishing medical, surgical, institutional, rehabilitation or other services to an ill defined class of persons who are unable to work because of disabilities that may be relieved or removed by such services. It does propose to (1) increase from \$3,800,000 to \$5,820,000 the appropriation authorized by the Social Security Act for maternal and child health services; (2) increase from \$2,850,000 to \$3,870,000 the appropriation authorized by the act for the purpose of enabling each state to provide medical, surgical, corrective and other services and care and facilities for diagnosis, hospitalization and after-care for children who are crippled; (3) increase from \$8,000,000 to \$12,000,000 the appropriation authorized by the act to aid states, counties, health districts and other political subdivisions of the states in establishing and maintaining adequate public health services. S. 1021 has passed the House, extending the benefits of the United States Employees' Compensation Act to members of Officers' Reserve Corps and Enlisted Reserve Corps. S. 2353 has passed the House, authorizing a federal appropriation for the construction, rehabilitation and installation at Carlisle Barracks, Pennsylvania, of a medical field service school, and such utilities and appurtenances thereto as may be necessary. S. J. Res. 107 has been reported to the Senate, proposing to authorize the President to award a gold medal of appropriate design to Dr. Anita Newcomb McGee "in recognition of her splendid service to the United States in organizing a corps of trained nurses for the United States Army during the period of the Spanish-American War and the Philippine Insurrection." H. R. 2296 has passed the House and Senate, proposing certain benefits to World War veterans suffering with paralysis, paresis or blindness or who are helpless or bedridden, notwithstanding misconduct.

Bills Introduced.—H. R. 6983, introduced by Representative Welch, California, proposes to authorize a federal appropriation to construct in California a marine hospital to be used

exclusively for the care and treatment of patients afflicted with tuberculosis. H. R. 6997, introduced by Representative Poage, Texas, proposes to create a pension system for adult cripples and for aged citizens in the amount of \$30 per month.

DISTRICT OF COLUMBIA

Changes in Status.—S. 1805 has passed the Senate and House, establishing a lien for moneys due hospitals for services rendered in cases caused by negligence or fault of others. H. R. 5238 has been reported to the House, with amendments, proposing to regulate the practice of optometry in the District of Columbia. As amended, the bill defines optometry "as the measurement and correction of refractive and muscular errors of the eye by any method not including the use of drugs and not including surgical procedures such as cutting or actual manipulation of the eyeball, but including the use of optical appliances for diagnosis or correction of such refractive and muscular errors."

Bills Introduced.—S. 2745, introduced by Senator King, Utah, and H. R. 7083, introduced by Representative Randolph, West Virginia, propose to authorize the Commissioners of the District to promulgate and enforce all such reasonable rules and regulations as they may deem necessary to prevent and control the spread of communicable and preventable diseases in the District of Columbia. The bill provides that it shall take effect from and after ninety days after its passage and approval, and that from and after the expiration of that period the following acts are repealed: (1) An Act to prevent the spread of contagious diseases in the District of Columbia, approved March 3, 1897; (2) An Act for the prevention of scarlet fever, diphtheria, measles, whooping cough, chicken pox, epidemic cerebrospinal meningitis, and typhoid fever, approved Feb. 1, 1907; (3) An Act to provide for registration of all cases of tuberculosis in the District, for free examination of sputum in suspected cases, and for preventing the spread of tuberculosis in the District, approved May 13, 1908; and (4) An Act for the prevention of venereal diseases in the District of Columbia, approved Feb. 26, 1925. H. R. 7086, introduced by Representative Vreeland, New Jersey, proposes to provide for insanity proceedings in the District of Columbia.

WOMAN'S AUXILIARY

Florida

The auxiliary to the Dade County Medical Association met in Coral Gables recently with forty-five in attendance. Mrs. W. S. Rosborough reviewed the book "Life and Death." The auxiliary will assist the medical society in the purchase of books and furnishings for the James M. Jackson Memorial Hospital.

Georgia

At the annual meeting of the auxiliary to the Medical Association of Georgia, Atlanta, April 25-28, the speakers were Dr. Grady Coker, president, and Dr. William H. Myers, president-elect of the Medical Association of Georgia, Mrs. Frank N. Haggard, first vice-president and chairman of organization of the auxiliary to the American Medical Association, and Mrs. W. K. West, president of the auxiliary to the Southern Medical Association.

Indiana

The auxiliary to the Marion County Medical Society held a public relations tea in Indianapolis March 13 attended by more than 200 members and guests. Dr. E. O. Asher of New Augusta addressed the group on "Advances in Scientific Control of Disease" and Harold V. Darnell on "Sanitation of Public Eating Places."

New York

The auxiliary to the Medical Society of the County of Broome was organized March 23 at Binghamton. Mrs. Daniel

Swan, president of the auxiliary to the Medical Society of the State of New York, and Mrs. Luther Kice, chairman of the organization committee, addressed the newly organized group on the aims and purposes of the auxiliary. Mrs. John H. Robertson was elected president.

The auxiliary to the Medical Society of the County of Albany met at the Joseph Henry Hospital recently. Dr. James F. Rooney, past president of the Medical Society of the State of New York, spoke on socialized medicine. Mrs. Frank Coughlin, chairman of the Hygeia committee, reported that a copy of *Hygeia* had been placed in every public, parochial and private high school in the County of Albany as the year's project of the auxiliary.

South Carolina

At the annual meeting of the auxiliary to the South Carolina Medical Association in Spartanburg April 12-13 Dr. E. A. Hines, chairman of the advisory council to the auxiliary, Dr. J. R. Des Portes, president of the South Carolina Medical Association, and Mrs. Charles C. Tomlinson, president of the auxiliary to the American Medical Association, were the speakers.

Dr. Roy D. Sumner spoke on socialized medicine at a meeting of the auxiliary to the York County Medical Society March 1. Mrs. J. L. Bundy, president, welcomed the presidents of local federated clubs, who were guests of the auxiliary at this meeting.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ALABAMA

Five Practitioners Honored for Research.—At the recent annual meeting of the Medical Association of the State of Alabama, citations were voted to five physicians for original research beneficial to mankind. According to the *Southern Medical Journal*, scrolls acknowledging the honor will be presented during July to the following:

Dr. George H. Searcy, Tuscaloosa (posthumously), for diagnosing and describing the first outbreak of pellagra in the United States in 1907.

Dr. Emit L. McCafferty, Mount Vernon, for early attempts at production and transmission of pellagra in 1907-1908.

Dr. Tom Douglas Spies, Cincinnati, for studies in the etiology, symptomatology and treatment of pellagra and allied nutritional diseases in Jefferson County, in 1935-1939.

Dr. Seale Harris, Birmingham, for first recognizing and describing a new disease entity, hyperinsulinism, in 1923.

Dr. Luther L. Hill, Montgomery, for first successfully suturing a heart wound in the United States in 1902.

CALIFORNIA

Typhoid from Domestic.—Two cases of typhoid were reported in children of two families in San Francisco recently. In both cases domestics in the families were proved to be carriers of *Bacillus typhosus*. One of the servants had a food handler's certificate from a health department, according to the *Bulletin* of the San Francisco County Medical Society.

Survey of Care of Mental Patients.—Dr. Walter L. Treadway, assistant surgeon general, U. S. Public Health Service, will make a survey of the care of mental patients at the University of California Medical School, San Francisco, and throughout the state. The survey is part of an examination of all the country's major public health facilities and activities that the public health service is making. At the medical school, where he is to be stationed for one year, Dr. Treadway is to make a special study of recent advances in care and treatment of mental patients made in the psychiatric division. Dr. Treadway has recently been medical officer in charge of the U. S. Narcotic Farm at Lexington, Ky.

CONNECTICUT

Personal.—The honorary degree of doctor of science was conferred on Ira V. Hiscock, C.P.H., New Haven, by Wesleyan University at its annual commencement June 18 in Middletown.—Dr. Maurice R. Moore, Norwich, has been appointed superintendent of the William W. Backus Hospital, Norwich.

First Outbreak of Smallpox in Six Years.—The investigation of a case of smallpox in Connecticut recently revealed the presence of five other cases, the first time the disease has been reported in the state in six years. According to the state department of health, the first case was in a Fairfield man who is a bus driver in Bridgeport. His three children later became ill one at a time, but his wife, who had been vaccinated, escaped. The man and his children had not been vaccinated. A relative from Bridgeport who visited the sick family became ill two weeks after the visit. This relative, on account of illness, went to the home of another relative in Stratford late in May. On June 15 a member of the Stratford family became ill and according to the bulletin of the state department of health July 3 is now under quarantine for smallpox. All the other patients have entirely recovered.

DISTRICT OF COLUMBIA

Commission on Mental Health.—Dr. Elmer Klein was appointed June 2 a member of the district commission on mental health, succeeding Dr. Loren B. T. Johnson, resigned. Dr. Bernard S. French, whose term had expired, was reappointed. The appointments were made by the district court for terms of four years beginning June 10. The commission was established a year ago to provide for the handling of insanity proceedings by experts.

Meeting of Railway Surgeons.—The forty-second annual meeting of the Association of Surgeons of the Southern Railway System was held at the Willard Hotel, Washington, June 13-15. Among the speakers were:

Dr. Muir Bradburn, New Orleans, Treatment of Fractures of the Shaft of the Femur.

Dr. James F. Mitchell, Washington, Conservatism in Traumatic Surgery.

Dr. William P. Herbert, Asheville, N. C., Abdominal Conditions as the Result of Trauma.

Dr. John R. Shacklette, Jeffersonton, Ky., The Prophylaxis and Treatment of Tetanus.

Dr. Albert C. Jackson, Jasper, Ala., What Should Organized Medicine Do About the Medical Indigent?

Dr. John B. Shoun, Elizabethton, Tenn., Our Contributions to Socialized Medicine.

Dr. Franklin Webb Griffith, Asheville, N. C., Socialized Medicine.

FLORIDA

Annual District Meeting.—The Northwest Medical District of the Florida Medical Association will hold its third annual meeting at the Community House, Marianna, July 20. Among the speakers will be:

Dr. Sidney G. Kennedy Jr., and Juriah H. Pierpont, Pensacola, Hemorrhage Complicating Empyema Thoracis.

Dr. Nathan S. Rubin, Pensacola, The Cross-Eyed Child.

Dr. Joe I. Turberville, Century, Fractures of the Pelvis.

Dr. James M. Hoffman, Pensacola, Back Pain.

Dr. Charles H. Ryals, Grand Ridge, Some Experiences of a Country Doctor.

GEORGIA

Calhoun County Drops Health Department.—At a meeting of the board of Calhoun County commissioners, May 9, it was decided to dispense with the county health department to curtail expenses, newspapers reported, effective July 1. Dr. George M. Anderson, Morgan, has been the health officer.

Changes in Health Officers.—Dr. Isbin S. Giddens, formerly of Ray City, has been appointed health commissioner of Jenkins County, with headquarters in Millen, succeeding Dr. Glenn J. Bridges, who resigned to become assistant health commissioner for Savannah and Chatham County.—Dr. Oliver W. Jenkins, Edison, has been named health commissioner of Bartow County. He will succeed Dr. Robert F. Young, Cartersville, who resigned to enter general practice in Hope, Ark.

IDAHO

Industrial Health Activities.—Dr. Samuel Weissross, director of the bureau of industrial hygiene in the state department of health, has resigned to enter private practice in Boise, according to *Northwest Medicine*. A conference of workers, employers and insurance carriers was held at the State House, Boise, to discuss measures which would reduce industrial health hazards in Idaho. The occupational disease law passed by the 1939 legislature was explained. The new law is the result of a survey made in 1938 which showed that 45,000 Idaho workers were exposed to industrial health hazards such as silicosis, lead and carbon monoxide.

ILLINOIS

Twenty-Six Teachers with Tuberculosis.—About one out of every 100 school teachers in down-state Illinois is believed to have active tuberculosis, the state department of health announced after studying the results of an examination of 2,818 persons at three state normal schools. A tuberculin skin test, followed by x-ray pictures of all positive reactors, was employed in the examination. The study disclosed twenty-six cases of active pulmonary tuberculosis, giving a rate of about 9 per thousand among the groups examined.

Chicago

Fellowship in Pediatrics.—The first endowed fellowship in pediatrics at the University of Chicago has been established by a gift of \$25,000 from the Benjamin J. Rosenthal Charities. The endowment will provide an annual fellowship of about \$1,000, it is reported.

Personal.—William H. G. Logan, D.D.S., M.D., has sailed for Europe to attend the meeting of the International Dental Federation, of which he is president. The meeting will be in Zurich, Switzerland, July 23-27.—The honorary degree of doctor of science was awarded to Dr. Andrew M. Harvey at the annual commencement of Knox College, Galesburg, June 13, in recognition of his work in industrial medicine. This was the fiftieth anniversary of his graduation from Knox.

Dr. Hoerr to Head Anatomy Department.—Dr. Norman L. Hoerr, assistant professor of anatomy, department of medicine, University of Chicago, has been appointed Henry

Wilson Payne professor of anatomy and head of the department at Western Reserve University School of Medicine, Cleveland. He will succeed the late Dr. Thomas Wingate Todd. Dr. Hoerr graduated at the University of Chicago in 1931. He has been a member of the department of anatomy since 1926 and assistant professor since 1933.

INDIANA

University News.—A special room for a study of the sterilization of air under the direction of Dr. Willis D. Gatch, dean and professor of surgery, Indiana University School of Medicine, Indianapolis, has been authorized as a research project, according to a recent report.—Albert H. Scheidt, assistant administrator of the Indiana University Medical Center, Indianapolis, for four years, had resigned to become director of the Chicago Hospital Council, effective July 1. He will be succeeded by Edmund J. Shea, chief medical librarian at the center since 1935.

Society News.—Dr. Ernest O. Asher, Indianapolis, recently addressed the Northeastern Indiana Academy of Medicine at Kendallville on "Gynecological Observations Made by Vaginal Examinations."—At a meeting of the St. Joseph County Medical Society, South Bend, May 23, Dr. Charles E. Savery, South Bend, discussed "Clinical Aspects of Allergy." At this meeting the society voted to employ an executive secretary.—Dr. Hugh W. MacMillan, Cincinnati, discussed "Deep Abscesses of Neck of Dental Origin" before the Dearborn-Ohio County Medical Society in Dillsboro recently.—Dr. George H. Garceau, Indianapolis, addressed the Wayne-Union County Medical Society in Richmond May 11 on "Diagnosis and Treatment of Knee Injuries."—At a meeting of the Jasper-Newton County Medical Society in Brook June 1 Dr. Warren Reynolds Hickman, Logansport, spoke on "Eye Diseases in General Practice."—The Elkhart County Medical Association was addressed in Elkhart May 25 by Drs. Carl P. Huber, Indianapolis, and Alfred S. Giordano, South Bend, on "Cancer as Related to Female Reproductive Organs" and "Laboratory Diagnosis of Cancer" respectively.

IOWA

Personal.—Dr. John C. Dennison, Bellevue, who has practiced in Jackson County more than fifty years, was guest of honor at the annual dinner of the county medical society June 1.—Dr. Thomas E. Eyres, Des Moines, the first director of the Polk County health unit, organized Aug. 18, 1937, has resigned to engage in private practice, it is reported.

Society News.—At a meeting of the Adair County Medical Society in Greenfield recently Dr. A. Fred Watts, Creston, discussed "Peculiarities of Symptoms in Children as Compared to Those in Adults."—Dr. William F. Braasch, Rochester, Minn., addressed the Black Hawk County Medical Society, Waterloo, recently, on dangers of delay in handling cases in which blood has appeared in the urine.—At a joint session of the Bremer County Medical Society and the staff of St. Joseph's Mercy Hospital, Waverly, recently, the speakers were Drs. Virgil S. Counsellor, on "Ovarian Neoplasms: Their Pathologic and Surgical Significance"; and Malcolm B. Dockerty, both of Rochester, Minn., "Special Ovarian Neoplasms."—The Johnson County Medical Society was addressed in Iowa City recently by Drs. James H. Allen on "Treatment of Conjunctivitis"; Alson E. Braley, "Differential Diagnoses of Cataract and Glaucoma," and Placidus J. Leinfelder, "Treatment of Minor Injuries." All are of Iowa City.—Dr. John D. Camp, Rochester, Minn., addressed the Woodbury County Medical Society, Sioux City, April 13, on "Malacic Diseases of the Bone."

KANSAS

State Board Appointments.—Recent appointments and reappointments to the state board of health include the following: Drs. Rolland W. Urie, Parsons; Harry L. Aldrich, Caney; Gilbert A. Leslie, McDonald; Jacob F. Gsell, Wichita; George I. Thacher, Waterville; Roscoe T. Nichols, Hiawatha; John L. Lattimore, Topeka; James T. Reid, Iola; William C. Lathrop, Norton, and Mr. W. E. Scott, Kansas City, attorney member. Reappointments to the state board of medical registration and examination include Drs. John F. Hassig, Kansas City; Chester E. Joss, Topeka; James E. Henshall, Osborne, and Dr. Omar L. Cox, Iola, is a new member. Other members of the board are Drs. Henry E. Haskins, Kingman; Mirl C. Ruble, Parsons, and Frederick S. Hawes, Russell.

KENTUCKY

Society News.—Dr. Oliver H. Perry Pepper, Philadelphia, addressed the Fayette County Medical Society, Lexington, at its annual dinner meeting June 13 on "Diverticulitis of the Colon."—Dr. Coleman C. Johnston, Lexington, addressed the Harrison County Medical Society, Cynthiana, at its June meeting on "Surgical Treatment of Bleeding Gastric and Duodenal Ulcers."

Personal.—Dr. John H. Rompf, recently a member of the staff of the Veterans' Administration Facility at Gulfport, Miss., has been appointed clinical director of the Eastern State Hospital, Lexington, succeeding Dr. Charles C. Phillips. Dr. Phillips resigned June 15 because of ill health.—Dr. Fred W. Rankin, Lexington, received the honorary degree of doctor of laws from the University of Maryland at the June commencement.

LOUISIANA

Society News.—At a meeting of the Orleans Parish Medical Society, New Orleans, June 12, Drs. Allan C. Eustis spoke on "Relation of Histamine to Asthma and Urticaria"; Guy A. Caldwell, "Use of Physiotherapy in Connection with Fractures and Injuries Involving the Joints," and Thomas Benton Sellers, "Hysterosalpingography."—At a meeting of the Ouachita Parish Medical Society May 4 Dr. George W. Wright, Monroe, among others, spoke on "Postoperative Thrombophlebitis."

Dr. Matas Honored.—A certificate of honorary membership in the American Association of the History of Medicine was presented to Dr. Rudolph Matas, New Orleans, at the annual dinner of the History of Medicine Society of Tulane University May 26, for work in having "preserved and passed on to generations of students the best traditions of medical humanism." Dr. Matas is professor of general and clinical surgery emeritus at Tulane. At this meeting it was announced that a freshman course in medical history will be introduced in the 1939-1940 school session.

MAINE

Anniversary of Memorial Library.—The Frederic Henry Gerrish Memorial Library observed its second anniversary with a special teaching clinic program at the Central Maine General Hospital, Lewiston, May 19. Dr. Jonathan C. Meakins, professor of medicine and director of the department, McGill University Faculty of Medicine, Montreal, conducted clinics, round table discussions and ward walks; he also addressed the evening session on "Doctors and Libraries." Dr. Willard H. Bunker, Calais, president of the Maine Medical Association, also spoke.

MARYLAND

Personal.—Dr. Arthur Karfgin, assistant medical director of the Maryland Casualty Company, has been appointed chief surgeon, succeeding the late Dr. Allen D. Lazenby, vice president and medical director, it is reported. Dr. Karfgin has been with the company since May 1, 1937.

Dr. Turner Appointed Professor of Bacteriology.—Dr. Thomas B. Turner of the International Health Division of the Rockefeller Foundation has been appointed professor of bacteriology at the Johns Hopkins University School of Hygiene and Public Health, Baltimore. The new appointment will be effective September 1, according to the Johns Hopkins University Gazette. Dr. Turner, a native of Maryland, graduated at the University of Maryland School of Medicine in 1925. From 1927 to 1932 he was Jacques Loeb fellow and instructor and associate in medicine at Johns Hopkins University School of Medicine, joining, in the latter year, the staff of the International Health Division of the Rockefeller Foundation. During the past three years Dr. Turner has been engaged in postgraduate teaching and research in syphilis at the school of hygiene and public health under the auspices of the foundation.

MICHIGAN

New County Health Unit.—The W. K. Kellogg Foundation will contribute to the cost of establishing a health unit in St. Joseph County and assist with its maintenance during the first year of operation. State and federal funds will also be forthcoming. Dr. Lawrence A. Berg, Menominee, has been named director of the new department. His appointment was effective June 1, when he commenced the organization of the new unit.

Members of State Medical Board.—Six new members have been appointed to the state board of registration in medicine by the governor: Drs. Elmer W. Schnoor, Grand Rapids;

Francis B. Jarzembowski, Detroit; William C. Ellet, Benton Harbor; Luther Peck, Plymouth; Horace L. French, Lansing; Garner M. Byington, Detroit. Reappointed members are Drs. J. Earl McIntyre, Lansing; Jacob D. Brook, Grandville; William E. Tew, Bessemer, and Claude R. Keyport, Grayling.

Hospital News.—The annual spring clinic of the Providence Hospital Internec Alumni Association, Detroit, was held May 7-11. One session was devoted to a discussion of pituitary disease by Drs. Mark R. McQuiggan, Russell T. Costello and Louis J. Bailey. Other speakers were Drs. Milton G. Schmitt, Chicago, on "The Determinates of Adequate Dosage in the Use of Short Wave Diathermy"; John S. Davis Jr., New York, "Rheumatism—Diagnosis and Treatment," and James F. Kelly, Omaha, "Use of X-Ray in the Prevention and Treatment of Certain Infections with a Mobile Unit."

Medical Secretary Appointed State Health Commissioner.—Dr. Henry A. Moyer, Charlotte, recently appointed medical secretary to the governor of Michigan, has been named state health commissioner to succeed Dr. Don W. Gudakunst, Lansing. He is personal physician to the governor. Dr. Moyer graduated at the Detroit College of Medicine, now the Wayne University College of Medicine, in 1901. He once served as health officer of Eaton County and was president of the Eaton County Medical Society from 1936 to 1938. He is 63 years of age. Dr. Gudakunst has been state health commissioner since February 1938.

MINNESOTA

Fund for Cancer Research.—A gift of \$14,400 has been given anonymously to the University of Minnesota Medical School, Minneapolis, to establish the Ivar Sivertsen Fund for cancer research. The fund will be administered by Drs. Harold S. Diehl, Ivar Sivertsen, Elexious T. Bell, Maurice B. Visscher, Owen H. Wangenstein and Karl W. Stenstrom, Ph.D., and will finance primarily a study of dietary and hormonal influences on malignant conditions.

Society News.—Dr. Hugo Theorell, head of the Nobel Biochemical Research Institute, Stockholm, Sweden, gave a Mayo Foundation lecture June 5 on "Structure and Function of the Yellow Enzymes." Prof. Ernst Laqueur, director of the Pharmacological Institute of Holland, Amsterdam, lectured on "Recent Advances in the Study of the Anterior Pituitary," May 22.—Dr. Leo G. Rigler, Minneapolis, delivered the presidential address before the annual meeting of the Minnesota Pathological Society May 16 on "Primary Carcinoma of Lung: Roentgenologic Manifestations."

MISSOURI

In Memory of Dr. Allison.—A bronze plaque, the gift of an anonymous donor, was presented to the St. Louis Medical Society April 25 in honor of the late Dr. Nathaniel Allison, at one time dean of Washington University School of Medicine, St. Louis. The presentation was made by Dr. Elsworth S. Smith. A graduate of Harvard Medical School, Dr. Allison served on the staffs of the medical schools of Washington, Harvard and Chicago universities. He was Chairman of the Section on Orthopedic Surgery of the American Medical Association in 1914. The bronze plaque is the work of Mr. Carl C. Mose.

NEW HAMPSHIRE

Clinic for Crippled Children.—The first orthopedic clinic held in the northern part of New Hampshire was conducted at the Littleton Hospital May 18 by Drs. Ezra A. Jones, Manchester, and Barbara Beattie, Littleton, the state board of health reports. Twenty-seven crippled children were examined. About half of these were children who had been traveling to the southern part of the state for examinations and treatment. About a fourth were children who had been receiving no treatment because of long distances and the remaining fourth were new patients. The state board of health furnished three nurses and the hospital extra nurses, x-ray and laboratory technicians.

NEW YORK

Hospital News.—The Oak Mount Sanatorium (Ontario County Tuberculosis Hospital), Holcombe, the first complete county tuberculosis sanatorium built in New York, was destroyed by fire May 31. Only three patients were confined to bed at the time and all were safely removed.—The cornerstone of a new \$900,000 building for the White Plains Hospital was laid May 21.

Alumni Meeting at Syracuse.—The alumni association of the Syracuse University College of Medicine held its annual dinner meeting in Syracuse June 5 with Dr. Frederick A.

Coller, Ann Arbor, Mich., as the guest speaker. Dr. Frederick W. Van Lengen, Syracuse, was elected president; Drs. Thomas F. Manley, Norwich; and Charles A. Gwynn, Syracuse, were elected vice president and secretary, respectively.

New York City

Institute for Hospital Administrators.—The first New York Institute for Hospital Administrators was held June 19 to July 1 at the College of Physicians and Surgeons of Columbia University under the sponsorship of the American College of Hospital Administrators and the Greater New York Hospital Association. Dr. Claude W. Munger, medical director of St. Luke's Hospital, was director of the institute. Lectures were presented in the mornings, field trips to hospitals took up the afternoons and there were round table discussions in the evenings.

Building for Hospital for Speech Disorders.—A new seven story building for the National Hospital for Speech Disorders was dedicated June 15. Dr. Bernard Sachs, vice president of the hospital, presided at the ceremonies. The new building, for which \$250,000 was given by Mr. Lucius N. Littauer, is the third home of the hospital. It was founded in 1916 by Dr. James Sonnett Greene, still the medical director. The new quarters contain an auditorium, kindergarten rooms and special rooms for group therapy, a research laboratory, an endocrinologic clinic and a recording studio, among other facilities.

Physical Examinations Required for Teachers.—Probationary teachers who come up for permanent licenses must hereafter pass a physical examination, it was announced by the superintendent of schools. Recent experiments with x-ray examination of new teachers revealed that nearly 2 per cent of the candidates had active tuberculosis. As a result, the board of examiners now requires all candidates to have x-ray examinations. Under the same order, principals are required to report to the medical staff of the board of education all teachers who are more than 65 years old, have become eligible for retirement because of service or are in any way mentally or physically unfit to teach.

Gifts to New York University.—Cash gifts and bequests amounting to \$111,617.72 have recently been announced by New York University College of Medicine. Among the larger gifts were:

Commonwealth Fund, \$8,525 for the department of preventive medicine and \$5,340.71 for research in obstetrics and gynecology under Dr. William E. Studdiford Jr.
Lucius N. Littauer, \$5,000 for the Dean John Wyckoff Memorial Fellowship Fund.
Mrs. Edith H. de Long, \$5,000 for the department of pediatrics under Dr. Charles Hendee Smith.
Lucius N. Littauer, \$1,500, Lederle Laboratories, \$1,000, and other \$1,236 for research on pneumonia under Dr. Jesse G. M. Bullowa.
Winthrop Chemical Company, \$6,000 for the department of the pteutics.
Friedsam Foundation, \$1,200 for the child neurology research fund.

More Beds for Tuberculous Patients.—The New York City Department of Hospitals has provided or has under way in a survey made in 1934 by a special committee with Dr. Haven Emerson as chairman. The new beds available or in prospect include: Bellevue, new building with 317 beds; Sea View Hospital, new pavilion with 250; Kings County Hospital, reconstructed building with 200 beds; Harlem Hospital, 40 beds set aside; Queens General Hospital, 32 set aside; City Hospital, 52 set aside; Neponsit Beach Hospital, 60 new beds to be added; Triboro Hospital, new 500 bed tuberculosis hospital under construction; Riverside Hospital, 110 bed unit soon to be started; alterations in progress to add 40 more beds at Willard Parker and 72 at Kingston Avenue hospitals. The department is now seeking appropriations for two 500 bed units for Harlem, the Bronx and Brooklyn. The waiting list of nonhospitalized cases May 1 was 379.

NORTH CAROLINA

Society News.—Dr. Douglas H. Sprunt, Durham, addressed the New Hanover County Medical Society, Wilmington, recently on "Increased Resistance to Infection Produced by Certain Endocrine Systems."—Dr. Merle D. Bonner, Jamestown, addressed the Guilford County Medical Society, Greensboro, May 4, on "The Use of the Bronchoscope in Conditions Other Than Foreign Bodies."—At a meeting of the Rockingham County Medical Society in Leaksville in May Dr. Kemp P. Neal, Raleigh, discussed recent advances in chest surgery.—Dr. Vance P. Peery, Kinston, was elected president of the North Carolina Hospital Association at the annual meeting in Winston-Salem in April.

Dr. Manning Retires.—Dr. Isaac Hall Manning, professor of physiology, University of North Carolina School of Medicine, Chapel Hill, since 1901 and dean of the school from 1905 to 1933, has retired from active duty and will be professor emeritus. Dr. Manning is a native of Pittsboro. In 1933 he was president of the Medical Society of North Carolina and has been president of the North Carolina Hospital Savings Association since its organization about 1935. Friends and former students from all parts of the state paid tribute to Dr. Manning at a dinner June 7. Among the speakers were Drs. Wingate M. Johnson, Winston-Salem; Hubert A. Royster, Raleigh; Wilburt C. Davison, Durham; William H. Smith, Goldsboro; John B. Cranmer, Wilmington; Foy Robertson, Durham, and Walter Reece Berryhill, Chapel Hill. Members of the faculty also honored him at a dinner.

OHIO

Public Health Meetings.—Dr. Charles A. Doan, Columbus, was elected president of the Ohio Public Health Association at its annual meeting in Columbus May 25-26. The guest speaker at the meeting was Dr. Esmond R. Long, Philadelphia, on "Problems of Tuberculosis Control." Dr. Doan and Dr. Roll H. Markwith, state director of health, spoke at the annual luncheon.—Dr. Holley H. Pansing, Dayton, was elected president of the Ohio Federation of Public Health Officials May 19 in Columbus. Among the speakers were Nathan Sinai, Dr. P. H., Ann Arbor, Mich., on "Public Health of Tomorrow," and Dr. Carl A. Wilzbach, health officer of Cincinnati, on the syphilis control problem in Cincinnati.

PENNSYLVANIA

District Meetings.—The Sixth Councilor District of the Medical Society of the State of Pennsylvania held its annual meeting at Birmingham, June 15. Drs. Lawrence W. Smith and William Wayne Babcock, Philadelphia, presented papers on "Effect of Temperature on Cancer Cell Growth" and "Recent Advances in Surgical Approaches" respectively. In the afternoon, Dr. Walter F. Donaldson, Pittsburgh, secretary of the state society, discussed the Wagner health bill; Dr. John J. Shaw, state secretary of health, the program of the state health department; Dr. David W. Thomas, Lock Haven, president of the state society, "Medicine Faces Crisis," and Mrs. Donaldson, president of the state woman's auxiliary, the program of the auxiliary.—A symposium on pneumonia was presented at the annual meeting of the Eighth Councilor District at Grove City June 21 by Drs. Edward L. Bortz and Leon H. Collins Jr., Philadelphia, and George J. Kastlin, Pittsburgh. A program on economics was presented by Drs. Charles H. Henninger, Chauncey L. Palmer and Walter F. Donaldson, all of Pittsburgh.—The annual meeting of the Ninth Councilor District was held in Indiana June 22. The scientific program included addresses by Drs. Ford M. Summerville, Oil City, on "Medical Testimony"; Kelse M. Hoffman, Franklin, heart disease and Belford C. Blaine, Pottsville, "Work Accomplished by the State Society Commission on Diabetes." Dr. John J. Shaw, state secretary of health, described the work of his department and Dr. David W. Thomas, Lock Haven, president of the state society, the activities of the society.

Philadelphia

Alvarenga Prize Awarded to Dr. Goldblatt.—The College of Physicians of Philadelphia announces that the Alvarenga Prize for 1939 has been awarded to Dr. Harry Goldblatt, professor of experimental pathology and associate director of the Institute of Pathology, Western Reserve University School of Medicine, Cleveland, for his contributions to knowledge of the pathogenesis of hypertension. The Alvarenga Prize is awarded each year on July 14, the anniversary of the death of the donor, Pedro Francisco da Costa Alvarenga of Lisbon, Portugal, who was an associate fellow of the college. It is given to the author of "the best memorial upon any branch of medicine, which may be deemed worthy of the prize."

New Public Health Department.—The University of Pennsylvania School of Medicine has established a department of public health and preventive medicine, with Lieut. Col. Arthur Parker Hitchens, Medical Corps, U. S. Army, as head of the department and George S. Pepper professor of public health and preventive medicine. From 1920 to 1929 the university conducted a school of hygiene and public health. That course will be revived, it is reported, and all undergraduate courses in this field will also be placed under the new department. Colonel Hitchens has been assistant professor of military

science and tactics in the Reserve Corps at the university this year. He was for a number of years connected with the Mulford laboratories. From 1925 to 1929 he served as technical adviser in public health and sanitation on the staff of Gen. Leonard Wood in the Philippines.

SOUTH CAROLINA

Poliomyelitis Epidemic Decreases.—The poliomyelitis outbreak in South Carolina is decreasing, health officials reported early in June. At that time there had been ninety-nine cases in Charleston and forty-five outside the city. Orangeburg County had the largest number of cases—fourteen—of any single county, no other having more than four. Plans for rehabilitating the victims were begun immediately after funds amounting to \$15,300 were made available by the National Foundation for Infantile Paralysis and the Children's Bureau, U. S. Department of Labor. The services of orthopedic surgeons and pediatricians were made available and four orthopedic nursing supervisors were brought into the state from Boston and New York. Hospital care was provided in some cases. The orthopedic nurses have conducted an educational program for local public health nurses in addition to visiting patients.

TENNESSEE

Society News.—Dr. Edward Dunbar Newell addressed the Hamilton County Medical Society, Chattanooga, May 25, on "Indications for Drainage of the Common Bile Duct."—Dr. Clifton J. Reynolds, Bluefield, W. Va., addressed the Sullivan-Johnson Counties Medical Society in Kingsport May 3 on prostatism.—Dr. Lucius C. Sanders addressed the Memphis and Shelby County Medical Society May 16 on "Medical Diseases of the Colon."

Upper Cumberland Meeting.—The Upper Cumberland Medical Society held its forty-fifth annual meeting in Cookeville June 13-14 with the following speakers, among others: Drs. John T. Moore, Algood, on "Acute and Chronic Pericarditis"; Carl R. Crutchfield, Nashville, "Carcinoma of the Colon and Rectum"; Roscoe C. Gaw, Gainesboro, "Relation of Upper Respiratory Infection to Chest Pathology," and W. A. Howard, Cookeville, "Symptoms and Medical Treatment of Duodenal Ulcer." Officers elected were Drs. A. H. Crouch, Forbus, president; Edward D. Gross, Chestnut Mound, Lex Dyer, Cookeville, and O. Reed Hill, Lebanon, vice presidents, and Luther M. Freeman, Granville, secretary.

TEXAS

Changes in State Medical Board.—Dr. Clairice M. Phillips, Levelland, and E. W. Wilson, D.O., San Antonio, were recently appointed to the state board of medical examiners. Drs. Thomas J. Crowe, Dallas, secretary of the board, and Charles S. Carter, Bells, were reappointed for six year terms.

VIRGINIA

Society News.—Dr. Karl S. Blackwell, Richmond, was elected president of the Virginia Society of Ophthalmology and Otolaryngology at its annual meeting in Roanoke in May; Dr. George G. Hankins, Newport News, vice president, and Dr. Mortimer H. Williams, Roanoke, reelected secretary. Drs. Daniel B. Kirby, New York, and Edward A. Looper, Baltimore, were guest speakers.—At a quarterly meeting of the Southside Virginia Medical Association in Petersburg June 13 the speakers included: Drs. Edward H. Williams, Richmond, on "Psychopathic Conditions"; Halstead S. Hedges, Charlottesville, "Ocular Manifestations of Systemic Diseases," and Samuel A. Vest, Jr., Charlottesville, "Uses of Sulfanilamide in Urology."

Changes in Health Officers.—Dr. William W. Fuller, Williamsburg, has been appointed director of the Peninsula health district to succeed Dr. Jack B. Porterfield, who has joined the staff of the state health department in Richmond.—Dr. Benjamin R. Allen, Chatham, formerly health officer of the Pittsylvania Valley district, has been appointed health officer of the Suffolk-Nansemond-Isle of Wight district, succeeding Dr. Thomas Scarlett. Dr. Scarlett has been assigned to the Rockingham County health district with headquarters in Harrisonburg. Dr. Wyatt E. Royce, formerly of Richmond, has been appointed to succeed Dr. James H. Gordon in the Alleghany-Botetourt district with offices in Covington. Dr. Gordon resigned to take graduate work in Philadelphia.

WISCONSIN

Society News.—Dr. Harold E. Marsh, Madison, discussed "Sulapyridine and Its Use in the Treatment of Pneumonia" at a meeting of the Columbia-Marquette-Adams County Medical Society May 16 in Portage.—Dr. Elmer L. Sevringhaus, Madison, addressed the Marathon County Medical Society, Wausau, May 23 on recent advances in endocrinology.

PHILIPPINE ISLANDS

Annual Medical Meeting.—The thirty-sixth annual meeting of the Philippine Islands Medical Association was held in Baguio May 2-5. The name of the organization was changed to Philippine Medical Association and the following officers were elected: Drs. Jose C. Locsin, Silay, president, reelected; Fernando D. Manalo, Baguio, and Bonifacio Mencias, Manila, vice presidents. Dr. Antonio S. Fernando, Manila, is secretary. Included on the program were the following papers:

- Drs. Antonio G. Sison, Jose K. Katigbak, Florencio N. Quintos and Manuel A. Hernandez, Manila, The Tuberculin Test at Various Ages: A Preliminary Report on the Study of a Phase of the Epidemiology of Tuberculosis in Manila.
Drs. Jose Albert and Florencio N. Quintos, Manila, The Use of Sulfanilamide.
Drs. Regino J. Navarro and Felipe B. Gomez, Manila, Studies of the Comparative Specificity of the Wassermann and Kahn Tests in Syphilis and Yaws.
Dr. Conrado T. Mata, San Juan del Monte, Thiamin Chloride in Infantile Beriberi.
Dr. Francisco T. Roque, Baguio, Influence of the Altitude and External Temperature on Blood Pressure.
Dr. Antonio Ejercito, Manila, Atabrine in Malaria Prophylaxis.
Dr. Fidel C. Plantilla, Cebu, Leprosy Transmission.
Dr. Jose C. Manalang, Culion, Fate of Culion Patients Presented to the Local Negative Examining Committee from 1922 to 1938.
Drs. Agerico B. M. Sison, Regino J. Navarro, Manila, and Delfin Ordoñez, Bacolod, Is True Pernicious Anemia Found in Filipinos?

GENERAL

Casselberry Prize Awarded.—The Casselberry prize of the American Laryngological Association, amounting to \$500, has been divided between Dr. Brien T. King, Seattle, for his operation to relieve abductor paralysis by use of the omohyoid muscle and Dr. Hermon Marshall Taylor, Jacksonville, Fla., for his film study of the hygiene of swimming.

Janeway Medal Awarded to Dr. Failla.—The American Radiology Society awarded its Janeway Medal for 1939 to Gioacchino Failla, Sc.D., physicist to Memorial Hospital for the Treatment of Cancer and Allied Diseases, New York, at the annual meeting in St. Louis May 15. Dr. Failla was at one time associated with Dr. Henry H. Janeway, for whom the medal is named.

Congress for Microbiology.—The third International Congress for Microbiology will be held at the Waldorf-Astoria, New York, September 2-9. More than 600 papers will be read. Any one interested in the subject may attend, an announcement emphasizes. Those who wish to attend should communicate with the treasurer, Kenneth Goodner, Ph.D., Rockefeller Institute for Medical Research, York Avenue and Sixty-Sixth Street, New York. The registration fee is \$5.

Society News.—The ninth annual convention of the Biological Photographic Association will be held at the Mellon Institute for Industrial Research, Pittsburgh, September 14-16.—The eleventh annual meeting of the Central Association of Obstetricians and Gynecologists will be held in Kansas City, Mo., November 2-4, with Dr. Edward A. Schumann, Philadelphia, as guest speaker.—The Pacific Coast Society of Obstetrics and Gynecology will meet in Portland, Ore., November 8-11.

Physicians Requested to Watch for Criminal.—The police department of Lackawanna, N. Y., requests that physicians watch for Lee Russell, a fugitive from justice who may seek treatment for a gangrenous ulcer. Russell is wanted by the police for murder. He is 44 years old, 5 feet 9 inches tall and weighs 146 pounds. He has light blue eyes, iron gray hair and is of medium build. His right leg has been amputated between the knee and hip and his right arm may be infected. He may seek treatment at government hospitals or may apply for treatment through welfare agencies. Physicians are asked to notify local police to apprehend Russell if he appears.

The Assets of American Foundations.—American foundations now have assets of more than \$1,200,000,000, according to a report recently published by the Raymond Rich Associates of New York. Of 243 foundations listed, 121 reported capital assets of \$945,443,637 at the end of 1937, the latest year for

which figures were available. For the other 122 that did not make public the extent of their assets, available information indicates that they aggregate about \$250,000,000. Among the largest were: Rockefeller Foundation, \$184,435,516; Carnegie Corporation of New York, \$163,841,376; General Education Board, \$54,607,431; Commonwealth Fund, \$51,830,504; Kresge Foundation, \$50,358,564; W. K. Kellogg Foundation, \$46,609,613; Carnegie Institution of Washington, \$36,506,669, and the Carnegie Foundation for the Advancement of Teaching, \$29,031,848. Certain foundations reported decreasing assets, most of them being those that have been appropriating from capital for project grants as a matter of policy.

Medical Program at Obstetrics Congress.—The preliminary program of the section on medicine of the American Congress on Obstetrics and Gynecology to be held in Cleveland September 11-15 has been announced. Among the papers listed are:

- Dr. David S. Hillis, Chicago, Treatment of Abortions.
Dr. Edwin M. Jameson, Saranac Lake, N. Y., Management of Tuberculosis Complicated by Pregnancy.
Dr. Howard C. Taylor Jr., New York, The Newer Conception of Ovarian Neoplasm.
Dr. John Rock, Boston, Diagnosis and Treatment of Ectopic Pregnancy.
Dr. John W. Harris, Madison, Wis., Practical Consideration of Labor Complicated by a Contracted Pelvis.
Dr. Edward A. Schumann, Philadelphia, Pathology and Treatment of Retained Placenta.
Dr. August A. Werner, St. Louis, Treatment of Menopausal Disturbances.
Dr. Samuel R. Meaker, Boston, Sterility in the Female.
Dr. Perrin H. Long, Baltimore, Sulfanilamide in Obstetrics and Gynecology.
Dr. Frank W. Lynch, San Francisco, Immediate and Remote Complications of Labor.

There will be also round table discussions each day at the noon hour on the following subjects: toxemias of pregnancy; genital infections; obstetric and gynecologic hemorrhages; the fetus and the newborn; forceps, occiput-posterior and breech presentation; anesthesia, analgesia and amnesia in labor.

Smallpox Reaches New High.—A total of 15,111 cases of smallpox was recorded during 1938 as compared with 11,687 in 1937 and 7,823 in 1936, according to the *Statistical Bulletin* of the Metropolitan Life Insurance Company. As usual, the states chiefly responsible for the high smallpox prevalence last year were those lying north of the Ohio and west of the Mississippi rivers. These states, whose total population is only slightly more than half of the entire population of the United States, reported 14,166 cases of smallpox in 1938 as against only 945 cases for the rest of the country. In contrast, not a single case of the disease was reported in New England, New York, Pennsylvania, New Jersey, Delaware, Maryland and the District of Columbia, the entire group accounting for a population of 39,000,000. New Jersey, with a population of about 4,400,000, has not had a single case of smallpox since 1931, while North and South Dakota, Montana, Idaho, Oregon, Wyoming and Utah, whose combined population is less than that of New Jersey, reported 12,666 cases during the same period. The *Statistical Bulletin* points out that New Jersey recognizes vaccination as a preventive of smallpox while the other seven states generally oppose compulsory vaccination. Three of the western states actually prohibit compulsory vaccination by statutory regulation, regardless of prevailing circumstances. The mild character of the prevailing smallpox is a factor in the complacent attitude of the western states. The avoidance of vaccination by so large a part of the population creates a fertile field for the spread from sporadic cases of malignant smallpox introduced from outside sources. The potentialities in this respect loom greater when the ease and rapidity of present day transportation are considered. Canada also showed an increase in 1938, recording 127 cases as compared with sixty-one in 1937 and sixty-two in 1936. However, the case rate was only 1.1 per hundred thousand as compared with 11.6 for the United States.

CANADA

Mickle Award to Dr. Best.—The University of Toronto Faculty of Medicine through its council has awarded the Charles Mickle Fellowship for 1939 to Dr. Charles Herbert Best, professor of physiology in the university, for his contributions to physiology, especially those related to diabetes and carbohydrate metabolism, to histamine and histaminase, to choline and fat metabolism and to thrombosis and heparin. The award is the income from \$25,000 bequeathed by the late Dr. William J. Mickle.

Foreign Letters

LONDON

(From Our Regular Correspondent)

June 17, 1939.

Clarification of the Abortion Law

The profession has felt for some time that the law of abortion should be amended. Two years ago the government appointed a committee of gynecologists, physicians, lawyers and persons in public life to inquire into abortion and consider what steps should be taken to reduce its mortality and morbidity. A year ago the subject came into prominence when a gynecologist, Mr. Aleck Bourne, was prosecuted for curteting a girl aged 14 who became pregnant after rape (*THE JOURNAL*, Aug. 20, 1938, p. 731). The law recognized only danger to life as justification for induction of abortion, and the prosecution stated that Mr. Bourne had never alleged that the operation was necessary to preserve life. Mr. Bourne, however, contended that the terror of the girl under the circumstances would be detrimental to pregnancy and labor and that he could not draw a line between danger to life and danger to health. His view was supported by other gynecologists, and the judge, after stating that a case had never come before a jury under similar circumstances, agreed with Mr. Bourne, who was acquitted.

The committee has now presented its report. Its most important recommendation is that the law should be so amended as to make clear that a physician who *bona fide* induces abortion to safeguard or restore the health of his patient commits no offense. In all cases of therapeutic abortion he should be obliged to obtain the written agreement of a colleague who has examined the patient and within forty-eight hours of operation should notify the local health officer. Two members of the committee dissented, because the proposal would not control unscrupulous practitioners and would in the public mind associate the health services with police functions. For some time a section of the medical profession has advocated relaxation of the law of abortion. The committee said "The induction of abortion is on ethical, social and medical grounds essentially an undesirable operation, justifiable only in exceptional circumstances," and it is "strongly opposed to any broad relaxation of the law designed to make social, economic and personal reasons a justification." It would welcome the legalization of abortion after rape but has been unable to devise a scheme to meet the legal and other difficulties. It does not support permission for the termination of pregnancies starting before the age of 16 or resulting from incest or likely to transmit hereditary disease, as has been advocated by some. One member dissented and would legalize abortion for women who had had four pregnancies which continued until the viability of the fetus.

Anorexia Nervosa Mistaken for Simmonds' Disease

Anorexia nervosa was first described and so named by the English physician Sir William Gull seventy years ago. His description has been overlooked in other countries; in Germany the disease has been confused with Simmonds' disease, an organic disease of the pituitary attended with wasting. Gull showed that anorexia nervosa is a functional disease depending on a morbid mental state. At the Royal Society of Medicine Prof. J. A. Ryle, opening a discussion, said that his observations show that 90 per cent of the cases occur in women, 70 per cent of whom are below the age of 30. Nearly all are unmarried. The majority may be classified as psychoneurotic but there are borderland graver cases which, as Ross has suggested, may be termed anorexia psychotica; but the adjective "nervosa" is sufficiently comprehensive to include both groups. In the etiology the emotional instabilities of young adult life play an important part. Among the contributory factors, other than "slimming," are love affairs, school attachments and jealousies

and unhappy home life; perpetuating factors include morbid enjoyment of the anxiety aroused by the illness.

The clinical picture is of a young woman in advanced starvation. The abdomen is scaphoid. The face is thin but the color is retained. There is fine downy hirsuties on the cheeks, forearms and back. The loss of weight is anything from 1 to 4 stone (6.35 to 25 Kg.). Amenorrhea is nearly constant. Emotional derangement is not far to seek. Under sensible institutional treatment the prognosis is almost uniformly good. Cases treated late or inadequately may be fatal—from simple starvation or from tuberculosis. The patient should be kept in bed at first. The treatment is feeding with straightforward explanation and assurance. Dr. J. H. Sheldon said that up to 1930, anorexia nervosa attracted little attention in Germany, being regarded as simply a curiosity in hysteria. Then came the description by Simmonds of the effects of destruction of the anterior pituitary, and physicians awoke to the fact that many young women were not only wasted but sometimes died of wasting. Knowing nothing of anorexia nervosa, many physicians were describing and are still describing these cases as examples of Simmonds' disease. Then anorexia nervosa was discovered and given a variety of names in Germany and Scandinavia. Sheldon examined the symptoms of anorexia nervosa in the light of what occurred in Simmonds' disease and starvation. These three have in common loss of weight, amenorrhea, lowered basal metabolism, alterations in carbohydrate metabolism, subnormal temperature, slow pulse and hypotension. In Simmonds' disease the body adjusts itself to a lowered food intake by a decrease of anterior pituitary activity. Anorexia nervosa may be regarded as functional Simmonds' disease, but it departs from the latter in one symptom; hirsuties is frequent but has never been described in Simmonds' disease. It is difficult to find what happens in famine. But in the Irish potato famine of 1845 hair an inch long on the face and arms of children was described. This increased growth of hair supports Sheldon's hypothesis that the body adapts itself to starvation by a series of coordinated changes. The hirsuties may be regarded as an unnecessary but inevitable by-product of increased activity of the adrenal cortex. Alone among the endocrine glands the adrenal enlarges in starvation.

Preparations for Civilian Air Raid Casualties

With the cooperation of the Medical Research Council, plans are being made for a national blood transfusion service to be used in the event of air raids. Volunteers prepared to become blood donors on the outbreak of war are to be registered. In view of the large number required, a committee of publicity experts has offered its services, in an honorary capacity, to make the scheme known. It is estimated that in the center of London alone 100,000 volunteers would be required, and in the area just outside London 80,000. In this area the Medical Research Council will set up special types of refrigerating plants for the storage of blood. Speaking at a meeting held in London, Dr. Janet Vaughan of the Medical Research Council did not think it an exaggeration that in the next war blood transfusions would be as important as bandages. The experience of the Spanish civil war showed that at least 10 per cent of the casualties could be saved by blood transfusion. The new service will be independent of any existing arrangements of the hospitals for transfusions under normal peace conditions.

In parliament the earl of Lucan, for the government, said that the work of providing 100,000 additional beds in existing hospitals for an emergency was well advanced; 150 institutions had been earmarked for upgrading, and arrangements were proceeding for the necessary adaptations and providing equipment. It had been decided to erect in England and Wales as soon as possible new hospital buildings in the form of huts for accommodating from 30,000 to 40,000 beds and in Scotland for 9,000 to 10,000 beds. Supplies, including blankets and pillows, drugs and dressings, will be distributed by the end of July.

The Order of Physicians

Belgium has just organized the Order of Physicians. Like France, Belgium did not have a constituted body charged with professional ethics. In these last years, however, the increasing importance enjoyed by physicians in France in the administration of social laws had opened the door to abuses which had to be repressed. With the cooperation of the medical syndicates, administrative boards were elected by their peers. The function of these boards was to maintain the fundamental ethics of the medical profession in their relations with the government or in all cases, increasingly numerous, in which the physician is not paid by the patient whom he treats. These boards constituted a sort of paternal jurisdiction. Their instruments were primarily persuasion and reprimand, but they could inflict more serious penalties. Their functions included the accidents of work involving the responsibility of physician to patient, care for the war victims, for which the state allows compensation, and social insurance. Besides, the syndicates had organized within their own organization what might be called family councils, which adjusted the differences arising between physicians and pronounced censure, though with no official validity. The syndicates also vigorously combated illegal practice but were checkmated by that form of charlatanism which flourishes under the protection of a diploma.

The Order of Lawyers is very old. It is chosen by the lawyers themselves and exercises a strict supervision over the members of the bar. But the governments that succeed one another in France, whatever their political tendencies may be, generally regard everything that tends to increase the independence of physicians with distrust. They accepted an Order of Physicians but wished to control it by the appointment of magistrates and functionaries as in England. The first draft establishing the Order of Physicians was prepared in 1842, but the medical profession was always opposed to it, wishing to retain control.

There has been much discussion of the Order of Physicians without leading to any agreement. Some find the role of the government tyrannical; others find fault with the pretensions of the physicians. Some physicians themselves affirm that the order would oppress the small fry and favor the bigwigs and hinder scientific independence. This is typical of French individualism. If by chance individualism came to be suppressed in the world, its last citadel would certainly be the medical profession. The activity of the syndicates finally surmounted these obstacles and in 1935 the chamber of deputies voted a law conforming or almost conforming to the wishes of the profession. It was adopted by the senate with some modifications. All that is needed now is the ratification by the chamber of deputies, which is not likely to be delayed. The law which goes into effect in Belgium is almost the same as the French law.

The French physicians will benefit by a tribunal which they themselves will elect and which will safeguard, for the benefit of all, the traditions of honor which constitute the foundation of medicine.

The Action of Sulfanilamides

Levaditi, Vaisman and Krassnoff have pointed out that sulfanilamides act by modifying the interior milieu, thus making it unfit for the multiplication of pathogenic micro-organisms and their capsulation. The micro-organism deprived of its capsulogenesis easily becomes the prey of phagocytes, and sterilization is thus obtained. These authors presented before the Académie de médecine the results of an investigation dealing with the bacillus of Friedländer. They inoculated peritoneally a number of mice, part of which were subjected to

sterilizing drugs. The majority of the animals were killed and examined after the start of the experiments. Bacillary capsulation was accomplished toward the fifteenth hour in the control subjects. In the treated mice poor capsulation toward the tenth hour was observed; this anomaly coincided with the influx of phagocytes into the peritoneum. The mice that were not killed got well. The process of healing was clearly marked on the one hand by involution of the micro-organisms and their capsulogenic faculty and on the other hand by contemporary intense phagocytosis of the micro-organisms. The capsule acts as an armor against the macrophages; in its absence the micro-organism behaves like a simple saprophyte. However, it was necessary to prove that phagocytosis does not depend on a change of the macrophages caused by the presence of the micro-organism; in other words, that it is the capsular protection and not the incapacity of the leukocytes which protects the micro-organism from destruction. Levaditi and his collaborators proved this by injecting into several mice a mixture of capsulogenic bacilli and of bacilli coming from a stock with weak capsulogenesis. After a given time the bacilli without capsules were devoured, while the others remained intact or almost intact. Every factor which directly or indirectly diminishes or suppresses the faculty of a micro-organism to form its own capsule in vivo comes to the aid of the defenses of the organism by making its micro-organisms vulnerable.

Tar on Roads and Cancer of Lungs

For years a recrudescence of primary pulmonary cancer has been observed in France. Kling, Samssonov and Héros think that one of the causes of this increase is the tarring of roads. Statistics offer little to confirm the responsibility of tar. Kling and his collaborators do not propose to proscribe tarring but they would like to see employed only innocuous substances. Benzopyrene contained within the tar used nowadays has a high cancerigenic effect on animals, inducing cancers of the epidermal epithelioma type. Benzopyrene can be mixed accurately with tar. Its proportion is about 0.5 per cent. Since from 2 to 3 Kg. of tar is spread over a square meter, one can gage the amount of benzopyrene used. Benzopyrene adheres solidly to particles of silica and other materials spread over roads. The benzopyrene-impregnated dust raised by the wind can be borne a great distance from its source and carry with it the harmful tar. The remedy for this danger, according to the authors of this communication to the Academy of Medicine, is the use of substances devoid of cancerigenic properties. A certain number of substitutes for tar in use at present for the coating of roads, such as natural pitch and petroleum resin, do not cause cancer in animals.

Meeting of Insurance Physicians

With Sir Walter Langdon-Brown and Paul Hörnig as honorary chairmen and Professor Loeper as actual chairman, the second international meeting of physicians on the staffs of life insurance companies was held recently. Sixteen countries were represented. The principal question was no doubt that of mortality exceeding expectancy calculations, or the increased risk assumed in permitting persons whose health is not absolutely normal to benefit from the advantages of life insurance by allowing them to pay the premium corresponding to their age, whereas in fact they represent a greater risk than their age indicates. The computation of the adjusted age necessitates considerable statistical labor, the results of which control the individual appraisals. Additional topics were hyperthyroidism, disorders of the metabolism, decreased mortality from tuberculosis and its causes, insurance rates for persons of excess weight, tobacco and its effects (which seem to have been exaggerated), albuminuria and the science of statistics, which ought not to be considered as in opposition to clinical procedure but associated with it and the importance of which will

be all the more significant as its methods become more generalized and standardized. The next meeting will be held in Rome in 1942.

Rheumatism

In the *Revue du rhumatisme*, Coste estimates the cost of rheumatism in different countries. In England it is 17 million pounds. In Germany 10 per cent of the workmen of Berlin incapacitated by diseases suffer from rheumatism. In Sweden nearly 6 million crowns is spent on it. In the United States rheumatism is estimated to cost about \$200,000,000. In France in 1936 one of the leading social insurance fund organizations found that rheumatism accounted for 36.8 per cent of the total days of illness, without including the expenses for hospitalization and unavailability. The average duration of treatment or unavailability for work was sixty-five days. In a large Paris factory the rate of unavailability on account of rheumatism was 21.26 per cent. In Paris hospitals rheumatic patients cost more than 10 million francs annually. Rheumatic endocarditis, however, tends to decrease in frequency and represents about 10 per cent of all cardiac disorders. The other forms of rheumatism are constantly increasing. These figures justify the active campaign undertaken at present against rheumatism in France. According to Lacapère, rheumatism ought to be attacked first of all by making available special services. It is necessary also to improve the hospitalization of rheumatic persons, to utilize therapeutically the warm springs with which the country is well endowed and finally to build centers of convalescence in order to restore the patient to economic life as far as possible. Social organizations have an important role in this plan, for it goes beyond purely medical limits. It is no less important to educate the public regarding rheumatism.

Warsaw, June 4, 1939.

Research on the Gonadotropic Effect of Tumors

Dr. J. Flaks and A. Ber performed at the Institute of Histology of the Warsaw University research on the relation between malignant tumors and the action of the gonadotropic principles of the hypophysis. In previous experiments the authors found that the gonadotropic principles of the hypophysis did not exert their usual influence on the genital system of mice which had been grafted with sarcomas of Ehrlich. Injections of as much as 500 rat units of gonadotropic substance did not result in growth of the graafian follicle in such mice, estrogen production and estrual changes in the vagina or in development of a corpus luteum. Since injections of estrogen were followed in these mice by the usual estrual changes in the vagina, the lack of such changes after administration of gonadotropic principle alone seems to be due rather to the influence of the tumor on the ovary. This interference of tumors with the gonadotropic principle occurs only if the sarcoma has grown to a sufficient size and its weight exceeds one fifth of the whole body weight of the mouse. The authors divided this inhibiting influence of tumors into two elements: the anti-A factor, interfering with ovulation, and the anti-B factor, interfering with the development of the corpus luteum. To determine the clinical value of these observations, methyl alcohol extract from urine of patients with malignant tumors was injected into mice receiving simultaneously gonadotropic substance. The authors examined lately the effects obtained by injection of urine extracts of 112 patients: sixty-three with cancers, forty with other diseases and nine healthy subjects. There were some differences between the influence of gonadotropic substance on mice with ingrafted tumors and on those receiving injections of urine extract of cancerous individuals. Since in the latter the urine extract of corpora lutea, it might not interfere with the development of corpora lutea, it might be assumed that the extracts from urine of patients with can-

cers contain only the anti-A agent. The presence of this factor was stated in 81 per cent of urines of persons with cancer and in only 27.6 per cent of persons with such diseases as tuberculosis, diabetes, stomach ulcer and heart failure, and in no urine of normal subjects. Further research is necessary to examine conditions in which there appears to be a positive inhibiting reaction in noncancerous individuals.

Treatment of Burns from Irradiation

Skin burns from x-rays are often resistant to any attempt at treatment. Good effects of blood transfusion in one case of x-ray burn was reported some years ago by Dr. F. Zalewski from Lwów, Poland. Dr. F. Łukaszczuk, director of the Warsaw Radium Institute, reported recently on the effects of blood transfusions in seven cases. The transfusions were administered repeatedly in amounts of from 100 to 150 cc. of blood per dose. Prompt healing and cicatrization occurred in all cases, although the burns had been resistant to other methods of treatment.

OSLO

June 14, 1939.

Norway Regulates Psychoanalysis

Psychoanalysis having run riot in Norway for several years to the financial benefit of the psychoanalyst, the inevitable reaction has set in. Dr. Ragnar Vogt, professor of psychiatry at the University of Oslo, in 1937 publicly denounced a state of affairs little short of scandalous. Psychoanalysis, he said, had become a vogue, a tragic feature of which was the evolution of an interminable chain of psychoanalysts. The patient who was analyzed yesterday set himself up today as a psychoanalyst. Professor Vogt drew attention to the possibility of curbing the activities of these amateur psychoanalysts by legislative measures. July 15, 1938, effect was given to this suggestion in a royal edict. According to this edict, which is supplementary to earlier legislation of 1927 and 1936, psychoanalysis is defined as a process which is continued for some time and which aims to clarify, interpret or otherwise influence unconscious mental processes. Psychoanalysis thus defined must not be undertaken even by doctors unless they have been given special permission by competent authority. In 1927 legislation was adopted limiting the activities of qualified doctors in certain fields in which they did not have the competence of specialists. This legislation aimed to prevent bodily injury to patients under the care of doctors without special knowledge of dangerous therapeutic measures. The legislation of 1938 extended this principle to the prevention of grievous mental injury. The Oslo Faculty of Medicine appointed a committee of three members to aid the country's medical director in working out rules to govern the activities which a doctor may or may not undertake without special permission. Henceforth if a psychoanalyst is challenged in connection with his treatment of patients he may appeal to the crown against the rulings of his judges. Perhaps the mere prospect of a prosecution and punishment has curbed the mere outrageous psychoanalytic offenders.

Infectious Abortion in Cattle

The state veterinary director, Dr. Thorshaug, is having success in his campaign against brucellosis in cattle, which started in 1935 and was based on far reaching propaganda and educational activities, the slaughter of infected cattle, the disinfection of suspected buildings and utensils, and compensation by the state for the farmer. He had made a census of infected herds based on the notification of veterinary surgeons who had tested cattle on a large scale. By the beginning of March 1939 the state had contributed 1,869,235 kroner (\$439,830), of which as much as 1,474,683 kroner (\$346,993) had been spent on payments to farmers for the slaughter of 15,894 infected cattle. There are about 200,000 herds in Norway with some 1,328,000 head of cattle. Since 1935 the number of herds found to be infected

has been 3,014, and early in 1939 approximately 95 per cent of these herds had been cleared of the infection. There are still a few herds containing positive reactors but the number is being rapidly reduced. Dr. Thorshaug's program is now being held up in Denmark as a model to be followed in that country. Enormous losses have in the past been inflicted on the Norwegian farmer by infectious abortion, which now soon will be extinct.

COPENHAGEN

(From a Special Correspondent)

June 23, 1939.

Legislation on Abortion

The new pregnancy law of May 18, 1937, has come under such effective controversial fire that its application has been repeatedly postponed, on the last occasion to Oct. 1, 1939. Meanwhile the principles underlying this law continue to be debated. The framers of the new law have taken the precaution to eliminate all financial temptations from the doctor who has to decide whether an abortion should or should not be induced in a given case. This precaution means that abortions can be induced under the new law only in hospitals and similar institutions which are run by the state or the local authorities. At a recent meeting of the Danish Surgical Society the speaker traced the evolution of this problem during the past few years, noting that, as a rule, the large surgical and gynecologic hospitals in Denmark have adopted a reticent attitude, being far more conservative in their indications for the induction of abortion than a group of doctors whose ignorance of gynecology seems to have been no barrier to their enterprise as abortionists. According to the new law a woman may secure the termination of her pregnancy if it is considered necessary to save her life or to ward off danger to her health. With a law susceptible of elastic interpretation, it has seemed desirable that there should not only be no pecuniary advantage accruing to the doctor who induces the abortion but also that in doubtful cases two or more doctors of high standing should consult together before the final decision is taken.

The Campaign Against Gonorrhea

At Department H of the Rigshospital, in the charge of Professor Haxthausen, a system has been employed since September 1937 of making a routine search in the town for sources of infection with gonorrhea. The young men attending this outpatient department are questioned by a doctor, in the presence of no third person, about the conditions under which they believed infection took place. With the necessary practice, discretion and sympathetic interest, it has proved possible to elicit the desired information in most cases. Dr. Esbern Lomholt has collected the experiences of this department in the course of a year and has undertaken a statistical study of the 361 men who came to it suffering from recently acquired gonorrhea. In 202 cases they gave the names and addresses of women suspected of infecting them. Notices sent by the hospital to these women led to 177 of them coming to the hospital to be examined. Gonorrhea was found in 154 of them, i. e. in 87 per cent. This high percentage of positive results is in large measure a tribute to the value of routine culture tests for gonococci. Among seventy-six wives and sweethearts examined, as many as fifty were found to be suffering from gonorrhea which had presumably been contracted during the incubation period of the disease in their male partners before they came to the hospital.

Dr. Lomholt has failed to observe a single case of gonorrhea in which prophylactic measures had been effectively adopted. But what is the use of any prophylactic device when it is neglected or followed only half-heartedly by a man more or less under the influence of alcohol? Of 278 patients infected by casual intercourse with a known or unknown woman, prac-

tically all had consumed alcoholic drinks, and more than two thirds had been drunk in some degree. With only one exception, the patients were found to have some knowledge of venereal disease prophylaxis. Dr. Lomholt is therefore skeptical as to the value of educational propaganda for the public in this field, and he is more hopeful with regard to improvements in the diagnosis and treatment of gonorrhea and in the conditions enabling the patient to come under skilled treatment. In other words, advances in the knowledge of the doctor are likely to be more helpful than advances in the knowledge of the patient about this particular disease.

The Training of Young Surgeons

The young doctor who wishes to make a career for himself as a surgeon has to produce acceptable evidence of work in exclusively surgical hospital services when applying for a senior appointment. His work in a mixed hospital service counts little or not at all, however dominating the surgical activities and however subordinate the medical activities of such a service may be. This ruling means that the heads of provincial mixed hospital services cannot keep their first assistants for long; they pass on as soon as they can to a purely surgical service, deserting the head of the mixed service as soon as he has trained them and has learned to rely on them to act effectively in his absence. A hospital surgeon, Dr. Jacob Nordentoft, has lately protested against this state of affairs and has pointed out that though his service provides more than a thousand operations a year and ample facilities for surgical experience, the medical cases, to which he cannot refuse admission, act as a blight on his assistants' careers, though a certain mixture of medical among surgical cases should help to give perspective and promote accurate differential diagnoses. The remedy for this trouble should be simple enough in his opinion. It would be to create two distinct services in the same hospital, with a surgeon responsible for the surgical cases and a physician for the medical cases.

Marriages

HOWARD C. HIGH JR., Grand Rapids, Mich., to Dr. ANNE VIRGINIA LUFKIN of Northfield, Minn., June 19.

RICHARD WHITE HANCKEL JR., New York, to Miss Ruth Bernice Farmer at Salisbury, Conn., May 13.

DE WITT CORNELL DAUGHTRY to Miss Lucille Carr, both of Clinton, N. C., in Richmond, Va., June 3.

JAMES MADISON KENNEDY JR., Superior, Wis., to Miss Barbara Chesney of Pittsfield, Mass., June 3.

JAMES ROBERT THOMPSON, Miles City, Mont., to Miss Verneil Baird of Barberton, Ohio, in April.

HENRY WILLIAM TEN PAS, Clymer, N. Y., to Miss Edna Mae Mooi of Holland, Mich., June 19.

HANFORD LOUIS AUTEN, Topeka, Kan., to Miss Dawn Elaine Seavers of Bridgman, Mich., in May.

HARRY C. GOLDBERG, Perth Amboy, N. J., to Miss Mildred Gruessner of New Brunswick, June 7.

RUFUS JUDSON PEARSON JR., Miami, Fla., to Miss Emily Timmerman of Atlanta, Ga., May 20.

PAUL W. BOWDEN, Arlington, Va., to Miss Adelia Angel Kobelson of Pueblo, Colo., in April.

DONALD SHEPHERD GROVER to Miss Hilda Viola Anderson, both of Syracuse, N. Y., July 1.

JOHN FRANCIS SULLIVAN, Boston, to Miss Margaret Carr of Dorchester, Mass., recently.

JAMES S. LYONS, Albany, N. Y., to Miss Mary O'Brien of Hoboken, N. J., April 29.

FREDERICK R. SMITH, New Paris, Ohio, to Miss Wilma Price at Indianapolis recently.

JOHN DALE OWEN, Milwaukee, to Mrs. Jean C. Burkhart of Toledo, Ohio, May 23.

LESLIE M. BELL, Dozier, Ala., to Miss Marion Willard at Andalusia, June 7.

Deaths

Herbert Weston McLauthlin, Denver; Harvard University Medical School, Boston, 1882; member of the Colorado State Medical Society; professor of pathology and histology, 1884-1885, professor of obstetrics and diseases of women and children, 1885-1893, professor of materia medica, clinical medicine and therapeutics, 1893-1894, and professor of principles and practice of medicine, University of Colorado, 1894-1896; professor of therapeutics and materia medica, Colorado College of Dental Surgery, University of Denver, 1897-1930; commissioner of health of Denver, 1885-1887; on the staffs of the Denver General Hospital, St. Luke's Hospital, Mercy Hospital and St. Joseph's Hospital; aged 84; died, April 30, of myocarditis.

Birge Carlton Swift, Middleville, Mich.; Detroit College of Medicine, 1903; member of the Michigan State Medical Society; past president of the Barry County Medical Society; formerly village president and member of the school board; served during the World War; on the staffs of the Pennock Hospital, Hastings, St. Mary's Hospital, Grand Rapids and the Veterans Administration Facility, Battle Creek; aged 61; died, April 1, in Grand Rapids.

Lawrence Dade Alexander ♂ New York; University of Virginia Department of Medicine, Charlottesville, 1901; University and Bellevue Hospital Medical College, New York, 1902; member of the American Laryngological, Rhinological and Otolological Society; fellow of the American College of Surgeons; on the staff of the New York Eye and Ear Infirmary; aged 60; hanged himself, April 23, at Wilton, Conn.

Clarence Dunbar Hart ♂ Savannah, Ga.; Albany (N. Y.) Medical College, 1931; secretary of the Luce County (Mich.) Medical Society; member of the Michigan State Medical Society; councillor of the twelfth district of the Michigan State Medical Society; health officer of Savannah and of Chatham County; formerly district health officer at Newberry, Mich.; aged 43; died, April 9.

Albert Husted Rodgers, Corning, N. Y.; Albany (N. Y.) Medical College, 1896; New York Homeopathic Medical College and Hospital, New York, 1898; member of the Medical Society of the State of New York; formerly member of the board of health; served during the World War; on the staff of the Corning Hospital; aged 71; died, March 16, of heart disease.

Charles Porter Osteen, Sumter, S. C.; University of Nashville (Tenn.) Medical Department, 1892; member of the South Carolina Medical Association; past president of the Sumter County Medical Society; on the staff of the Tuomey Hospital; aged 72; died, April 14, in a hospital at Tampa, Fla.

George M. Studebaker, Erie, Pa.; Baltimore Medical College, 1896; member of the Medical Society of the State of Pennsylvania; for many years member of the city board of health; formerly on the staff of the Hamot Hospital; aged 72; died, March 9, of cerebral hemorrhage and arteriosclerosis.

Robert Calvin Cook, Springfield, Ill.; University of Louisville (Ky.) Medical Department, 1909; member of the Illinois State Medical Society; pediatrician of the division of child hygiene and public health nursing, department of public health; aged 57; died, April 13, of coronary occlusion.

Robert Chalmers Robe, Pueblo, Colo.; Rush Medical College, Chicago, 1895; member of the Colorado State Medical Society; formerly city and county physician; on the staff of St. Mary's Hospital; aged 75; died, April 1, in the Parkview Hospital of empyema and lobar pneumonia.

Hirsch Sadowsky ♂ Miami Beach, Fla.; Fordham University School of Medicine, New York, 1917; for many years on the staffs of St. Joseph's Hospital, Lebanon Hospital and Lincoln Hospital, New York; aged 55; died, April 2, of hypostatic pneumonia and cerebral hemorrhage.

Peter J. McHugh, Fort Collins, Colo.; Detroit College of Medicine, 1889; member and past president of the Colorado State Medical Society; past president of the Larimer County Medical Society; formerly mayor of Fort Collins; aged 75; died, April 5, of uremia and arteriosclerosis.

Charles Beaufort Jackson, Jasper, Ala.; Atlanta Medical College, 1886; member of the Medical Association of the State of Alabama; on the staff of the Walker County Hospital; aged 76; died, April 14, in the Baptist Hospital, Birmingham, of ulcer of the duodenum and uremia.

William Alfred Cerswell, Toronto, Ont., Canada; University of Toronto Faculty of Medicine, 1901; M.R.C.S., England, and L.R.C.P., London, 1902; fellow of the American College of Surgeons; surgeon to the Grace Hospital; aged 61; died, April 30, of heart disease.

Adam William Schreiber ♂ Lafayette, Ind.; Washington University School of Medicine, St. Louis, 1903; served during the World War; aged 59; on the staff of the Lafayette Home Hospital, where he died, April 14, of ruptured appendix with abscess and coronary disease.

Hillis Delbert Rigterink, Grand Rapids, Mich.; University of Michigan Medical School, Ann Arbor, 1937; member of the Michigan State Medical Society; aged 26; on the staff of St. Mary's Hospital, where he died, April 19, of cholelithiasis and streptococcal peritonitis.

Isaac Warner Knight ♂ Pitman, N. J.; Hahnemann Medical College and Hospital of Philadelphia, 1903; past president of the Gloucester County Medical Society; district health officer; served during the World War; aged 56; died, April 10, of coronary embolism.

James McDonald Scott, Chicago; Rush Medical College, Chicago, 1896; on the staffs of the Mother Cabrini Memorial Hospital and the Frances Willard Hospital, now known as the Loretto Hospital; aged 73; was shot and killed, April 24, by an unknown assailant.

Charles Sumner Lane ♂ Hudson, Mich.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1902; aged 72; died, April 16, in the University Hospital, Ann Arbor, of cerebral hemorrhage and essential hypertension.

Thomas Eli Craig ♂ Sabina, Ohio; College of Physicians and Surgeons, Baltimore, 1892; past president of the Clinton County Medical Society; formerly member of the local board of education; aged 73; died, April 2, of mitral insufficiency and chronic hepatitis.

Walter James Irwin ♂ Cleveland; Cleveland College of Physicians and Surgeons, Medical Department Ohio Wesleyan University, 1904; on the staff of the Glenview Hospital; aged 60; died, April 6, in the Mount Sinai Hospital, of hypertension and arteriosclerosis.

Jacob Osmund Lunn, Harbor Beach, Mich.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1908; member of the Michigan State Medical Society; aged 53; died, April 9, of a self-inflicted bullet wound.

Frazier N. Cloyd ♂ Danville, Ill.; University of Louisville (Ky.) Medical Department, 1893; on the staffs of the Lakeview and St. Elizabeth's hospitals; aged 70; died, April 18, of acute nephritis, hemolytic streptococcus sore throat and acute otitis media.

William Johnston, Hardy, Ark.; Kentucky University Medical Department, Louisville, 1903; member of the Arkansas Medical Society; past president of the Lawrence County Medical Society; aged 62; died, April 14, of coronary occlusion.

Samuel H. Miller ♂ Joplin, Mo.; Missouri Medical College, St. Louis, 1899; an Affiliate Fellow of the American College of Surgeons; on the staffs of the Freeman and St. John's hospitals; aged 77; died, April 8, of heart disease.

Edward William Phifer, Morganton, N. C.; North Carolina Medical College, Davidson, 1902; member of the Medical Society of the State of North Carolina; medical director of the Grace Hospital; aged 62; died, April 23, of heart disease.

Frank John Iuen, Kansas City, Mo.; Medical College of Ohio, Cincinnati, 1887; member of the Missouri State Medical Association; aged 76; died, April 14, in the Trinity Lutheran Hospital of chronic nephritis and prostatic hypertrophy.

Henry Wheeler McComas ♂ Oakland, Md.; University of Maryland School of Medicine, Baltimore, 1888; formerly mayor, county health officer and state senator; aged 74; died, April 10, of carcinoma of the prostate with metastasis.

Wallace C. Sarber, Argos, Ind.; Fort Wayne College of Medicine, 1896; member of the Indiana State Medical Association; aged 66; died, April 5, in the Parkview Hospital, Plymouth, of unresolved pneumonia and acute myocarditis.

Jay R. Douglas, Osawatimie, Kan.; Eclectic Medical University, Kansas City, Mo., 1914; Kansas City (Mo.) College of Medicine and Surgery, 1919; member of the Kansas Medical Society; aged 52; died, April 12, of heart disease.

Ralph Higgins Barker ♂ Derry, N. H.; Dartmouth Medical School, Hanover, 1900; past president of the Rockingham County Medical Society; aged 66; died, March 21, of bronchopneumonia and carcinoma of the intestine.

DEATHS

249

- Clarence C. Bassett**, Goodland, Ind.; Wisconsin College of Physicians and Surgeons, Milwaukee, 1906; member of the State Medical Society of Wisconsin; served during the World War; aged 59; died, April 18, of coronary thrombosis.
- Henry Ulysses Robinson**, New York; Long Island College Hospital, Brooklyn, 1905; member of the Medical Society of the State of New York; aged 55; died, March 20, in the Mount Sinai Hospital of coronary thrombosis.
- John Newell Holcomb**, Grand Rapids, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1902; served during the World War; aged 61; died, April 25, of coronary thrombosis and arteriosclerosis.
- James Edward Hulett**, Hattiesburg, Miss.; Cleveland Homeopathic Medical College, 1905; Barnes Medical College, St. Louis, 1906; aged 56; died, April 18, in the Methodist Hospital of acute intestinal obstruction.
- James W. Crawford**, Coldwater, Mich.; Vanderbilt University School of Medicine, Nashville, Tenn., 1877; formerly member of the state legislature; aged 86; died, April 13, of hypertension and intestinal hemorrhage.
- George B. McClellan Reese**, Brazil, Ind.; National Normal University College of Medicine, Lebanon, Ohio, 1893; at one time president of the board of health of Clinton; aged 69; died, April 11, of cerebral hemorrhage.
- Edwin Membrane Trook**, Marion, Ind.; Rush Medical College, Chicago, 1892; member of the Indiana State Medical Association; veteran of the Spanish-American War; aged 76; died, April 12, of heart disease.

Correspondence

SUBSIDIES FOR MEDICAL RESEARCH

To the Editor:—Daily I, along with thousands of other physicians, receive reprints of articles written by physicians but distributed by drug manufacturers or medical and surgical supply companies. The public press daily contains many articles recommending these medicines or appliances. It is now generally known that these articles and recommendations are frequently subsidized. Experience has demonstrated that too frequently the recommendations have been influenced by the subsidy.

In my opinion these concealed subsidies are a disgrace to our profession and should be declared unethical and suppressed in all quarters. If an article is published which reports investigations that have been subsidized by a company or an individual, a footnote should so state, along with the amount of the subsidy.

J. ARTHUR BUCHANAN, M.D.,
510 Ocean Avenue, Brooklyn.

URINARY CONCRETIONS AND SULFAPYRIDINE

To the Editor:—In the last issue of the *Proceedings of the Society for Experimental Biology and Medicine*, Antopol and Robinson (40:428 [March] 1939) and Gross, Cooper and Lewis (p. 448) reported that "urinary concretions" could be demonstrated in animals that had been given sulfapyridine. Several months ago, crystals were found by me in the urines of patients receiving this drug. A study on the effect of this drug on the urinary tracts of monkeys was in progress about the same time as that of the experimenters quoted. Similar results were obtained. Since my conclusions only confirm those of the authors quoted, the details of my experiments need not be related.

Fig. 1.—A, stone in enlarged ureter at arrow; B, dilated ureter.

At autopsy I found needle-like crystals and crystals in the form of sheaves similar to tyrosine crystals in the urine; concretions in the bladder, the ureter and the pelvis of the kidney; secondary infection of the bladder and ureters; dilatation of the pelvis of the kidney; pyelonephritis; markedly hyperemic swollen and enlarged kidneys, and hypertrophy and dilatation of the gallbladder and its ducts. Some of the stones found were large enough to occlude the ureters and the urethra. They were

found in greatest number in the trigon area of the bladder but never in the gallbladder. During life there was a consistent decrease in the hemoglobin and in the total number of red cells.

The bladder of the experimental animals was occasionally found to be dilated and contained from 10 to 30 cc. of residual smoky urine which was bloody on gross and microscopic exami-

Fig. 2.—A, enlarged hyperemic kidney; B, dilated stone-filled ureter; C, dilated gallbladder; D, slightly dilated ureter.

nations. In *THE JOURNAL*, May 6, page 1820, Southworth and Cooke described hematuria as a complication following the use of sulfapyridine in human beings. Gerstenberger (*Tr. Am. Pediat. Soc.*, April 1939) reported that Fulton and his associates at the Babies and Childrens Hospital at Cleveland had encountered hematuria in five, or 18.5 per cent, of twenty-seven cases of pneumonia in children who had been treated with this drug. Lawrence (quoted by Antopol and Robinson) has also described hematuria. The sodium salt has been used in subsequent experiments with similar results (Toomey, J. A.; Reichle, H. S., and Takacs, W. S., in preparation).

It is believed that sulfapyridine should be used with care or not at all in treating patients who have nephritis or urinary retention secondary to prostatitis or paralyzes and the like. I mention retention since I have found that one of the easiest ways to produce stones is to cause retention of the urine in the bladder. This can be brought about in *Macacus rhesus* monkeys weighing from 3,000 to 5,000 Gm. by giving them experimental poliomyelitis, a condition often accompanied by dilatation of the bladder and retention. Five-tenths gram of sulfapyridine given to such animals twice a day over a period of from five to seven days invariably causes the production of stones. The doses used are greater comparatively than those used in man; yet if the drug is used long enough the human dosage may approximate the totals used in animals. However, such large amounts would never be given to human beings in so short a period of time.

In *THE JOURNAL* May 13, page 1934, Wagner mentions the use of this drug in cases of poliomyelitis seen early in the

Fig. 3.—Type of stones obtained (magnification about 2 diameters).

disease. It has been shown, however (J. A. Toomey and W. S. Takacs, in press) that this drug has no effect in preventing the experimental disease in *Macacus rhesus* monkeys even when it is given beginning four days prior to the onset of paralysis. In fact, because of the urinary retention often present in animals which have experimental poliomyelitis, the use of this drug may even aggravate the clinical condition, and the animals treated may succumb earlier than the controls.

It is sometimes believed that fewer complications follow the use of sulfapyridine than the use of sulfanilamide. This may be true as regards the number of complications, but the kind of complications that are now being described as occurring in experimental animals that have received this drug and the fact that it is excreted so erratically would make it one to be used with a great deal of caution. When it is employed, the urine should be examined twice and the blood once a day. If for any good reason it is administered to a patient with paralysis, especially to a person with signs of urinary stasis or retention, it should be used with extreme caution and the dangers appreciated.

JOHN A. TOOMEY, M.D., Cleveland.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

TREATMENT AND PREVENTION OF POISON OAK AND POISON IVY DERMATITIS

To the Editor:—Will you tell me the accepted idea as to the treatment of poison oak by injections and also the value of injections in prevention?

M.D., Virginia.

ANSWER.—Reports on the efficacy of injections of rhus toxins for the treatment or prevention of dermatitis due to poison ivy, poison oak or poison sumac vary widely in the hands of different investigators. Among the many factors influencing the result of clinical investigation one should not overlook the mental one: the person who goes to the trouble of taking prophylactic treatment is much more apt to avoid contact with these plants. Although no conclusion can be reached until further evidence is available, in spite of the strong experimental testimony against the value of toxin treatment it seems impossible to discount wholly the testimony of clinicians that protracted cases of ivy dermatitis have cleared promptly after the toxin treatment was begun. Some reports also offer strong evidence that prevention is possible in a high percentage of susceptible individuals. A number of poison ivy and poison oak extracts have been accepted by the Council on Pharmacy and Chemistry for inclusion in New and Nonofficial Remedies.

VIABILITY OF TUBERCLE BACILLI—BUILDING DISINFECTION

To the Editor:—A man with advanced and open pulmonary tuberculosis, recent owner of a small apartment hotel, has just vacated the building, in which he occupied one apartment and supervised the care of the bedding and the cleaning in others. He had constant access to the cellar containing elaborate piping, coal bins, stoker and several areas of dirt flooring; also to the hallway and the stairs, which are dark, damp and inaccessible to daylight or direct airing, with a temperature range between 60 and 70 F. The new owner with several small children in the family plans to occupy the vacated apartment with the children having more or less unavoidable access to the places described. Will any practical method of disinfection render the quarters safe for immediate occupancy by small children? Is any reliable information available as to the duration of viability of the bacillus of tuberculosis in the environment described? What part would lapse of time have in advice to the new owner under the present circumstances?

M.D., Washington.

ANSWER.—Numerous studies have been made on the viability of tubercle bacilli under various atmospheric conditions. Cultures exposed to direct sunlight in summer are rendered sterile in about two hours. When sputum containing tubercle bacilli is spread thinly on glass and exposed to the direct sunlight in summer, the bacilli are destroyed in ten minutes. On clothing it may require as long as from twenty-four to thirty hours of direct sunlight exposure during the summer months to destroy them. Ultraviolet rays produced by the mercury quartz vapor lamp brought in direct contact with tubercle bacilli kills them in about ten minutes. When sputum containing tubercle bacilli is spread on cloth or glass and dried at a low temperature with only dim sunlight, the bacilli may be alive and virulent from two to four months later. When exposed to diffuse light, such as in the apartment mentioned, tubercle bacilli have been found virulent for nearly six weeks; but beyond two months the disease cannot be produced by introducing them into the bodies of guinea pigs.

Freezing apparently has little or no effect on the viability of tubercle bacilli. Even the temperature of liquid air maintained as long as eight days has not been found to kill bacilli in tuberculous lesions. Heat in a moist environment is effective; in fact, at 95 C. one minute suffices.

There is serious doubt whether fumigation of any kind is adequate in a building such as the one described. In the apartment actually occupied by the patient the best procedure would be to expose all the furniture and bedding to the direct rays of the sun for several days. If this cannot be done a mercury quartz vapor lamp might be used. Such lamps can be rented through physician and hospital supply houses. At a distance of 30 inches from the object, five minutes of this light is equal to about an hour of ordinary sunlight. It would be well to wash the floors and woodwork thoroughly with soap and water and also revarnish or paint them and redecorate the walls and ceilings. Of course, if the rooms are not occupied for approximately two months all bacilli will probably be dead as a result of exposure to indirect sunlight. In the other rooms and apartments where the patient came in contact with the bedding direct sunlight or ultraviolet rays from a special lamp would increase the safety if they are to be occupied immediately. Ordinary window glass obstructs ultraviolet rays of sunlight to a considerable extent and these are the most important germicidal rays.

The most difficult problem is in the cellar, where there is absence of sunlight. Here there is the possibility of bacilli remaining alive over a period of three or four months. To destroy them at once, one would be compelled to resort to ultraviolet rays produced by a special lamp.

TREATMENT OF SHORTENED LEG AFTER POLIOMYELITIS

To the Editor:—What is the opinion on shortening the good leg in young persons with shortening of one leg due to infantile paralysis?

H. G. Snyder, M.D., Seneca, Kan.

ANSWER.—In cases of infantile paralysis in children in which there is 1½ inches or more of shortening there are three methods of approach:

1. To lengthen the paralyzed leg after the manner of Abbott.
2. To shorten the sound leg by shortening the femur. This can be shortened as much as 2 or 2½ inches without great difficulty.
3. To put a short bone graft across the epiphysal line of the condyle of the femur, on the inner and outer aspects, and also on the head of the tibia. This operation results in early union of the epiphyses of these two bones and the result is about 2 inches of shortening, which occurs over a period of

about two years. Phemister devised this operation; it can be performed on children around the ages of 10 or 12 years.

For about sixteen or seventeen years Ober has been shortening the lower leg on the sound side. This is believed better than shortening the femur because it is easier to control. The shortening operation takes less time for recovery, and it is probably wiser to shorten the sound leg than it is to lengthen a paralyzed leg in which there is no muscle power. The one objection to shortening a sound leg is that patients often dislike having normal structures operated on for fear that something untoward may happen.

POISON OAK DERMATITIS

To the Editor:—I have recently treated a man aged 45 for meningomyelitis which developed about a week after three injections of poison oak vaccine were given for a moderately severe case of poison oak dermatitis. I should like to know whether there are any cases reported in the literature in which, following poison oak vaccinations, inflammatory lesions of the spinal cord and meninges have developed. I should also like to know whether there have been cases reported of inflammation of the spinal cord and meninges following severe cases of poison oak dermatitis.

M.D., California.

ANSWER.—A search of the literature has revealed no reference to cord or meningeal lesions following poison ivy or poison oak dermatitis or after the administration of the toxins of these plants for therapeutic purposes. In his book on the effects of these toxins, J. B. McNair (*Rhus Dermatitis*, Chicago, University of Chicago Press, 1923) mentions three fatal cases; but the original reports of these cases proved to be brief and without detail, except that one patient died at the end of the third week and another patient lingered with great suffering for two months and then died. The third case is given in even less detail: A man went to sleep in a patch of poison ivy and died as a consequence. Besides the dermatitis, fever, rapid pulse and respiration, constipation or diarrhea, albuminuria or suppression of urine, swollen lymph glands and insomnia are listed as symptoms of severe poisoning.

Severe irritation of the kidneys has been produced in laboratory animals. No symptoms suggesting involvement of the nervous system are mentioned.

CARE OF RABBITS IN PREGNANCY TEST: RABBITS FOR CANCER TEST

To the Editor:—How long should female rabbits be isolated before being used for the Friedman test for pregnancy? How soon after a rabbit has been used for a Friedman test that gave a positive result can it be used a second time? How soon after a rabbit gives birth to a litter of young can it be used for a Friedman test? Should it be kept in a pen with other female rabbits or in a separate pen? Is it true that the odor of a male rabbit, as for instance in an adjacent pen separated by a wire partition, will produce corpora hemorrhagica in a female rabbit? I have recently heard of using twelve day pregnant rabbits in testing for a malignant condition. The story I heard was that urine from a patient who has cancer, when injected into the blood stream of such a rabbit, will cause the rabbit to abort. What evidence is there of the reliability of this test?

L. A. Crowell Jr., M.D., Lincolnton, N. C.

To the Editor:—A few weeks ago there was reported in the newspaper some observations made by the American Academy of Science in which a new test for carcinoma was described. This test was to inject a sample of urine from a patient into a pregnant rabbit. If the patient had carcinoma, the rabbit would abort. Is there any reasonable basis for this story?

Warner Ogden, M.D., St. Paul.

ANSWER.—Female rabbits to be used for the Friedman test must be isolated from both males and other females for four weeks. The same length of time must be allowed to elapse after a rabbit has been used for a previous test and after pregnancy. This isolation is necessary because ovulation has been known to have been produced by the rabbit merely smelling a male penned close by or by being jumped on by another female. In order to obviate the possibility of obtaining false positive tests careful workers have adopted the modification of the Friedman test described by Schneider. In this procedure the previously isolated female is operated on and the ovaries are inspected immediately prior to the injection of the urine. In this way it is impossible to get a false positive reaction. Another safeguard that is used in certain laboratories makes the obtaining of a false negative reaction impossible: A small number of rabbits are known to be refractory to the anterior pituitary-like substances in pregnancy urine. In order that such refractoriness has not been responsible for the negative reaction obtained, every test that is negative is checked by injecting urine from a known pregnant woman into the same rabbit. If the second test is negative one is dealing with a refractory rabbit, and the test must then be repeated with another animal.

The test for cancer was reported by Elsasser and Wallace in *Science* (89:250 [March 17] 1939). These authors describe their test as a "selective action of urine and serum from patients with malignant tumors of embryonal and new growing tissues." The technic of the procedure is to inject 20 cc. of the patient's urine daily into the vein of a twelve day pregnant rabbit for four days. On the fifth day the rabbit will abort. Urine from patients with many types of cancers, teratoma of the testicle, dysgerminoma of the ovary and Wilms tumor all produced abortion. Control urines from normal and pregnant persons did not produce this effect. Serum from these same persons gave the same results.

The urine injected into these rabbits causes a progressive placental necrosis starting at the inner border of the decidua cells and advancing until it involves the entire embryonal mass. When this urine is injected into nonpregnant rabbits it produces degeneration of the graafian follicle, especially marked in the granulosa area. When it is injected into male rabbits the testicles undergo degeneration and the process of spermatogenesis completely disappears.

As a check on the test the authors injected a combination of 500 units of a solution of anterior pituitary-like substance and 20,000 units of estrogenic substance daily into pregnant rabbits without producing abortion.

This work appears to be well controlled and is interesting, but until reports from other observers and over a great number of cases are at hand it is not recommended as a diagnostic procedure.

TEMPERATURE OF DRINKING WATER

To the Editor:—What should be the temperature of drinking water for men working at an indoor occupation, in this case, in a woodworking plant? The artesian tap water runs at about 68 F. The men are not satisfied with this water and claim it is too tepid. I have advised against the use of ice water and have suggested that the water should be at about 55 or 60 F. This is assuming that they drink as much water as they desire. Is the drinking of ice water under these conditions objectionable?

H. R. Sugg, M.D., Clinton, Iowa.

ANSWER.—Most people in this country are conditioned to drink water so much cooler than the normal human body that a distinct and usually pleasant sensation of cold in the mouth, throat and esophagus is produced during and for a minute or two after such water drinking. This acts as a counterirritant, obscuring the sensation of thirst, and hence tends to produce the impression that the real thirst is stopped almost at once with cold water but not with tepid or warm water. The real need of the body for water is met by water within the temperatures not actually injurious to the mucous membrane of the digestive tract. There is no reliable evidence that "ice water" (water at from 37 to 50 F.) causes chronic injury to the alimentary tract. Taken in large quantities with a meal, it probably, through cooling, slows down gastric digestion for a few minutes. But this is probably of little practical significance. If taken in large quantities (from three to four glasses) and rapidly, water near the temperature of ice may induce, in addition to a painful cold sensation, a temporary spasm of the pharynx and esophagus as well as of the stomach, or even acute dilatation of the stomach in some people, especially when the body temperature is above normal, and as a consequence reflex excitability is somewhat increased. We eat ice cream, and the Eskimo eats frozen meat, without evident injury. So it seems that the temperature of ingested water is primarily a matter of habit and convenience, not a matter of health, and has no relation to a person's occupation.

TREATMENT OF ROUNDWORMS

To the Editor:—A woman aged 45 has for four years had vomiting of roundworms. Only rarely does she pass any in the stools. She has had santonin, chiniofon, hexylresorcinol, ascaridol, and recently carbon tetrachloride. After she has taken these drugs she vomits several dead worms and passes a few also by rectum, but after a week or two vomiting of worms again commences. Due precautions have been taken against reinfection. Can you suggest any further treatment?

M.D., England.

ANSWER.—In the course of treating more than 3,000 cases of ascariasis with hexylresorcinol, in which egg counts were done both before and after treatment, several cases were said to be resistant to hexylresorcinol treatment. It was found however that, if these patients followed directions exactly, the parasites could be removed. In such cases it is necessary that the drug be given on an empty stomach in the morning following a light evening meal and that no food be taken for four or five hours after the treatment is given, although as much water as desired may be taken. A single treatment is usually sufficient, but in

QUERIES AND MINOR NOTES

253

special cases a second dose of hexylresorcinol may be given forty-eight hours later to insure success.

Crystalline hexylresorcinol must be used. The pills should be relatively freshly made. If given in crystalline form, the drug may be taken in hard gelatin capsules. Incorporating it in oil or any other vehicle will reduce, if not obliterate, activity. Since treatment with hexylresorcinol is said to have been ineffective in this case, it would seem advisable to give a bismuth subcarbonate meal in order to determine whether or not the parasites might reside in some abnormal pocket of the intestinal tract. Since ascariads are known to ingest bismuth, such a meal might also locate the worms.

There is so much evidence that hexylresorcinol will kill ascariads if it comes in contact with them that it is probable that patients can be cured if every precaution is used to see for oneself that all details are attended to.

REVERSE QUECKENSTEDT TEST FOR SPINAL BLOCK

To the Editor:—What are the steps in doing a reverse Queckenstedt test in suspected spinal block?

M.D., Connecticut.
